It is strange therefore that though every student during his training is expected to know how a gastrectomy and an arteriogram are done—operations which none will ever have to perform without further postgraduate training—sex and marriage are touched on only briefly as an incident in clinical teaching. His instruction is still too often based on organ dysfunction rather than on the treatment of the patient as a whole, and where the two patients comprise the single entity of a marriage, such an approach is even more hopeless. As a rule, the illness encountered in a clinic is seen from the viewpoint of the specific organs in which that clinic specialises rather than as a syndrome of the whole person. The consequence is that most doctors who acquire any knowledge of sex by the time they graduate, do so, not by organised instruction in the subject but rather by personal enterprise. Not all doctors may be suited temperamentally for giving advice on this subject, but at least they should receive sufficient basic training to enable them to recognise not only their patient's difficulties but also their own inhibitions.

In an infertility clinic such as mine, where husbands and wives are seen together, and where an attempt is made to assess the marriage rather than one partner of it, many cases (which are referred apparently solely for sterility) are in fact found to have psychodynamic problems of marital disharmony which have unfortunately not been recognised either by the patient or the doctor. Worse still, advice has been disastrous in certain cases when given by a doctor insensitive to, or untrained in, the recognition of these emotional problems. This consideration led me to inquire whether medical education is adequate in these matters.

Instruction at Medical Schools

To ascertain the present position of medical teaching I asked forty seven medical schools in Great Britain and abroad to tell me what instruction is given in the following subjects:

1 The physical and psychological background of normal coitus and conception.
2 Contraception.
3 Sexual maladjustment and marital dysharmony.

Thirty six schools sent replies—twenty-four in Britain and twelve abroad. Of these, only two said that no instruction was given at all, one saying that it "was not desirable for students." But only five provided formal lectures on coitus and conception, though in a further six these topics were discussed in clinics. In twelve, one formal lecture was given on contraception, and in another seven clinical instruction was arranged. In seven, lectures were given on sexual maladjustment and in another five it was discussed in the clinics. Finally, the psychological problems of the background to marriage were discussed by none in formal lectures, but in fourteen these were mentioned in a general way during the course of clinical teaching. These figures suggest that probably less than half of the students at these schools have had anything like adequate instruction before they enter their professional life.

To compare the opinions of the students with those of their teachers, inquiry was made of graduates from five universities who had qualified in 1951–53. The teachers at these particular universities had informed me that such instruction was included in general clinical teaching, though not in systematic lectures, and they were satisfied that enough was taught. But at only one of the five was the training regarded as satisfactory by the graduates. At the four others, all the graduates said that they were dissatisfied and had in fact very little or no instruction.

We may compare this with the replies given to Ingleby (1952) on the teaching of teachers and clergy, who also have an influence on family life in the community.

Teachers

Of fifty-one training-colleges and seven university education departments, all except three deal with sex. The courses of instruction were divided by Ingleby into three groups. (1) Fifteen covered only anatomy and physiology and there were no other lectures. (2) Twenty-one discussed the psychological implications and gave training for sex teaching in a broad sense. Possibly this was done with an academic rather than a dynamic psychological approach, but at least an attempt was made to discuss emotional adjustments and sex relationships in terms of the students' own personal adjustments. (3) In ten, attempts were made to give a broader approach to sex in the wider setting of marriage and the family, in some cases this included a completely separate course of lectures.

Clergy

In sixteen out of twenty Church of England colleges, a course of 9–12 lectures with special references to the ethical and psychological aspects of sex and marriage was given. Other denominations gave some training on marriage but none was as adequate as the Church of England training.

From this it seems that doctors are the least equipped of the three professions dealing with these concerns of everyday life If in fact the main obstacle (apart from inertia) is the overburdened curriculum, surely the time has come to discard some of the traditional items in favour of what is of increasing importance in the modern world

This is not the place to outline all the psychosomatic syndromes likely to be encountered either in disguise or as diagnoses which the patients themselves make, such as impotence, frigidity, and vaginismus Such cases should obviously be treated by those who specialise in them, but it is astonishing how many such patients are still treated with tonics, sedatives, or just "reassurance" Once rebuffed they will rarely return to the same doctor for advice on such a matter, and when their difficulties continue for years they eventually become hopelessly incurable

My purpose is simply to state a case for the improvement of medical education on these topics, and to put forward suggestions for incorporation in the medical curriculum

Recommendations

The student should receive instruction in sex education and be helped to solve his own personal problems If he can understand himself, he is better able to understand others *an emotionally maladjusted student* will be a bad student and a worse doctor Each university should have an adviser for students, to whom they can bring their personal problems He would combine knowledge with understanding based on experience (An adviser whose advice is academic and who cannot perceive the unasked questions in the student's mind may be worse than no adviser at all Equally, the other type of adviser who gives the student a slap on the back and the hearty advice to "go out and get a woman" may also do serious emotional damage) Undoubtedly advisers with the right personal qualifications are scarce, but even so it seems that in many universities little attempt has ever been made to find them Here the local marriage guidance councils could help

Systematic lectures on the physiological and psychological background of normal coitus should be given to senior medical students The relation of sex to the larger sphere of family life and human relations should be explained, and a sense of perspective given of its relation to right living (At many schools such subjects as marriage guidance, premarital preparation, and marital dysharmonies do not seem to be covered) Systematic lectures should also be given on sexual maladjustments, coital technique, impotence, vaginismus, &c , by someone experienced in these subjects Each university library should contain a selection of books and pamphlets on all these subjects

Instruction in contraception is indicated—both theoretical (with a film) and practical (by attendance at Family Planning Association centres)

Lectures on the spiritual and psychological background to marriage, with special emphasis on normal relationships, could well complete the course

Lists of suitable books on sex and marriage problems may be had from the National Marriage Guidance Council, 78, Duke Street, London, W 1, or the "Alliance," 238, Edgware Road, London, W 2, free of charge

I should like to express my thanks to those University teachers who were kind enough to reply to my questionnaire

In England Now

A Running Commentary by Peripatetic Correspondents

IT all started with a seductive brochure from the Central Council for Health Education introducing the first of a series of make-it-yourself pegboard displays to peddle preventive medicine in the market-place A wave of nostalgia swept over my desk Far back in school days I turned the odd sixpence carving model *Dreadnoughts*, my undergraduate conception of an embryo in plasticine was an artistic gem, albeit introducing a revolutionary portrayal of the development of the human gut, post-war parental responsibilities saw Sunday afternoon struggles with balsa wood and dope in that era of model aircraft kits When plastics and puberty brought self-help to the young engineers, I retired from the bench to enjoy presbyopia and the caress of losing consciousness after lunch So it was a burst of boyish enthusiasm that ordered the pegboard display set Like all good secretaries, Miss McDour has a depressing flair for pointing out my limitations Monday morning found her viewing a huge parcel with extreme distaste before she flounced away to submerge herself in the typing pool The chief clerk's bald head peeped round the door and winked The office boy came to collect the wrappings, and the caretaker brought elevenses Our *quartet* knelt down on the floor to sort out the bits There were three sheets of instructions, including the old familiar command to have at hand scissors, razor-blades, sharp knives, strong glue, and a knitting needle The office boy startled me by producing a nicely mounted razor-blade and a flick knife from his pocket He knew where to borrow a knitting needle, his girl friend on the telephone switchboard is having a race with time to complete her trousseau, but she rallied to our call The great idea was to produce a three-dimensional effect of a couple of toddlers surrounded by the gin-traps of adult life, symbolised by boxes of matches, dangerous drugs and scheduled poisons, fireplaces and saucepan handles, surmounted by the heart-cry caption "Are they Safe at Home?"

I should never have let the chief clerk use the flick knife He sliced a chunk out of his thumb and spurted arterial blood all over the saucepan A tourniquet fixed him, but the model dropped below food-hygiene standards The office boy got more glue in his hair than on the cardboard, at least it stopped his forelock flopping By lunch-time we had finished cutting out I moved my desk over a hole in the carpet At 2 P M we returned to battle The junior typist, not long graduated from dressing paper dollies, joined the party She put some cold cream on my hand after we had mounted the matches display and learnt that these new glues are inflammable Pity about her eyebrows, but she can use a pencil The chief clerk consoled himself with a couple of aspirins from the poison tray The caretaker alone emerged unscathed The job looked very pretty We creaked ourselves proudly up from the floor at 5 P M Miss McDour minced frigidly to my desk with her calculation that our day's labour had cost the corporation well over £10 in salaries, about twice the price of the display set, and just think of a thousand local government offices frittering away their man-power and knitting needles But bandaged, burnt, and blistered as we were, we little band of health educators went off rejuvenated to the safety of our homes

* * *

Recently I met a young couple who had been guests at the Medical Research Council's Common Cold Research Unit at the Harvard Hospital, Salisbury They were enthusiastic, and said that they would like to pay another visit, taking their ten-year-old child with them I expressed doubts on the *wisdom* of this, but later I found my thoughts turning to the possibilities of research in infectious diseases in childhood What about a Mumps Prophylaxis and Treatment Research Unit for prepubertal males? Parents who had apparently failed to indoctrinate their boys with the mumps virus by close contact with their stricken school friends, could sign them up for a stay at Fat Face Farm, or Parotitis Place The major service would, of course, be to induce an attack of mumps in delightful surroundings Terms would depend on whether the patient stayed only until the onset of his parotitis, or until the attack was over, in the latter event, there would be a suitable reduction if he consented to act as contact-donor for newcomers An insurance could be taken out against the rare risk of orchitis at this age The research would include problems of contagion and tests of possible chemotherapeutic agents, though the number of test-subjects would, of course, have to be dovetailed in with the provision of enough donors If an isolated virus could be used, the administrative problems would be simplified Could the Medical Research Council please consider this idea ?

* * *

The account of my peripatetic colleague's brush with the Law (March 30) reminded me of a similar occasion which, however, had a happier outcome

I was bidden to attend at ten of the clock in the forenoon precisely before London's senior metropolitan magistrate—no less The summons added ominously, wherein fail not The charge Unnecessary Obstruction ("What is necessary obstruction ?" a colleague of mine had asked the magistrate some weeks earlier and had promptly been fined double the usual amount) I was indignant because my car was proximal to the yellow-band notice which guarded the entry of a small tributary into the major artery of traffic I was even more indignant because I was parked next to a large delivery-van which the policeman told me he would not be prosecuting

On receiving the summons therefore I rang up the motoring organisation to which I belong "Leave it all to us," they reassuringly said "No need for you to attend the court you will plead guilty of course " They were shocked when I said I had no *intention* of so doing A barrister friend of mine was of the same spineless mind "Don't be an ass," he advised "I'll represent you if you insist, but it will cost you a lot of money and the old basket will fine you three times as much " I therefore conducted my own defence When I pleaded not guilty, a sigh compounded of disbelief mingled with pity wandered around the court The magistrate looked profoundly sad The atmosphere reminded me of the occasion when the Snark pronounced judgment "When it said the word *GUILTY* the jury all groaned and some of them fainted away"

The police gave their evidence I cross-examined Was I close to a hospital ? Yes Did I ask the constable if he was going to prosecute the delivery van ? Yes Did he do so ? No Why not ? It was here that he made his fatal error "Well, that's different That chap's delivering goods " "Sir," I said, turning to the magistrate, "I submit that when I go to a hospital I also deliver the goods " The magistrate could be seen wrestling with himself Hardened inspectors blanched a passing cloud obscured the sun Suddenly the Great Man beamed "Well, well," he observed genially, "I know you doctors have to do your job Case dismissed "

News Release, New York (to be used on or after Feb 10, 1967)

After almost 5 years of intensive research by nearly 1000 company scientists in conjunction with hospital and university researchers the Pillum Ram Co today announced 'Multipanas,' an entirely new concept in medication In one pill it has been found possible to contain all the daily drug needs of the average American The 'Multipanas Magnatab' consists of an outer core containing 25 vitamins, 25 essential elements, aspirin, a tranquilliser, amphetamine, and bioflavinoids, whilst the delayed release' inner core contains barbiturates An ingenious label wrapping 3 times round the bottle makes it possible to list each ingredient so as to meet registration requirements In a companion product for those over 40 this balanced formula has been fortified by synthetic sex hormones with marked anabolic activity To devise and perfect this product researchers travelled over 600,000 miles Said the company's President "It is a pity circumstances did not permit them to travel further such products would never have been even thought of 10 years ago " The Pillum Ram Co has global branches and subsidiaries including The Pillum-Ram Co of England

Letters to the Editor

CÆSAREAN SECTION

SIR,—The picture painted by your leading articl (April 6) of maternal and fœtal risks of delivery by cæsarean section is black indeed, and some may fee that the dangers are exaggerated Crude morbidity figures are difficult to interpret and I have always found it hard to explain the high mortality-rate reported by Marshall and Cox,[1] whom you quote No practising obstetric surgeon could possibly accept a maternal death rate of 1% today In my personal series since 1943 of 1114 sections, 2 mothers have been lost

In one case a woman semiconscious after eclamptic convulsions died a few hours after delivery Necropsy showed a pontine hæmorrhage and a large subarachnoid hæmorrhage In the second case a primipara, exhausted by prolonged labour with an impacted breech presentation, died unexpectedly on the eighth day of the puerperium Necropsy showed a large pulmonary embolus, with extensive thrombosis of all pelvic veins, extending into the femorals In the first case, and perhaps also in the second, the operative delivery had little direct relation with the maternal death

I cannot believe that this experience is exceptional A similar criticism can be made of your quotation of a perinatal fœtal mortality-rate of 4 9% in Brooklyn I have not read Gordon's article[2] yet, but we may suppose that a high proportion of these infants were small prematures or otherwise prejudiced in some way Healthy mature infants should not be lost

It is easy to make further comments on controversial points in the operative technique you recommend Delivery of the fœtal head by the hand implies a uterine incision large enough to accommodate both hand and head at the same time It may be difficult to get the fingers below an impacted head and the uterine muscle is easily torn Some may feel that these are serious drawbacks, and that delivery by small Wrigley's forceps is more elegant and technically more sound Trendelenburg tilt of the table is permissible only if the patient is properly intubated with a cuffed tube Otherwise dangerous regurgitation of gastric contents may follow Ischæmic necrosis of the uterine muscle with continuous sutures is difficult to prove I have myself been well satisfied with continuous sutures On four occasions when I have been able to recover the uterus in later years, after a previous section, careful microscopic examination has failed to demonstrate any uterine scar It is necessary, however, to pay special attention to the strong fascia over the muscle, in order to obtain a perfect scar

Chobham Surrey L G HIGGINS

BENIGN MYALGIC ENCEPHALOMYELITIS

SIR,—The title of the paper by Dr Galpine and Dr Brady (April 13) and other reports[3] suggest that the term "benign myalgic encephalomyelitis" may find a place in medical terminology This name was first suggested in your leader last year[4] for a widespread epidemic disorder of presumed infective origin with the following clinical characteristics (1) symptoms and signs of damage to the brain and spinal cord in greater or lesser degree, (2) protracted muscle pain with paresis and cramp, (3) emotional disturbances in convalescence, (4) normal cerebrospinal fluid, (5) involvement, in some variants, of the reticuloendothelial system, (6) a protracted course, with relapses in severe cases, and (7) a relatively benign outcome

---

1 Marshall, C M Cox L W Transactions of the 12th British Congress of Obstetrics and Gynæcology 1949, p 30
2 Gordon C A *Amer J Obstet Gynec* 1957 73 65
3 Crowley N, Nelson, M, Stovin, S *J Hyg, Camb* 1957, 55, 102
4 *Lancet*, 1956, i, 789

With the lapse of time and the publication of accounts of the Royal Free epidemic,[3 5 6] the clinical similarities of the various outbreaks classified in group II of your leader have been underlined, and there seems a prima-facie case that they are similar in cause and pathology

As Sigurdsson [7] pointed out, there are obvious dangers in naming a disorder in which the ætiology and pathology are unknown There is always the risk that the name will turn out to be inaccurate There appear to be two alternatives (1) the disorder should be named after the place where it first appeared, or (2) a purely descriptive term should be applied on the basis of the known clinical characteristics—"an epidemic disorder characterised by disturbance of the central nervous system, painful muscles, a normal cerebrospinal fluid and often enlargement of lymph-nodes" (or, to contract, "epidemic ameningitic lymphoreticular myalgic encephalomyelopathy")

The first suggestion has the disadvantage of all eponyms it conveys nothing to the uninformed There is also some doubt in this instance which place name to apply. The second, although informative and accurate, is obviously impracticable Clearly some compromise between accuracy and brevity must be found "Benign subacute encephalomyelitis" has been suggested [8] This name has the advantage of conveying that the active course of the disease is often long, but unfortunately it also suggests that the outset is insidious (as in subacute bacterial endocarditis and subacute combined degeneration), which is far from the truth Crowley et al.[3] have suggested "lymphoreticular encephalomyelopathy", whatever its other merits may be, this name defies pronunciation and defeats memory

"Benign myalgic encephalomyelitis" has been criticised because the disease is not always benign, nor invariably myalgic, and possibly never encephalomyelitic Benignity is relative, and it seems to me that "benign" is sufficiently justified by the fact that there is no other recorded infective disease of the central nervous system without mortality As various authors [5 9 10] have stressed, the pain in this disease, although not invariably present may be devastating and is perhaps the feature which impresses itself most forcefully on the observer As far as the final term is concerned, the clinical impression that the lesion is central rather than peripheral is supported by the electromyogram There appear therefore, to be the alternatives "encephalomyelitis," which suggests an inflammatory lesion, or 'encephalomyelopathy," which implies a toxic or degenerative lesion In our present state of ignorance "encephalomyelitis" seems preferable because it conveys the suggestion that the disease is almost certainly infective in origin As Sigurdsson points out however, a final decision must await the examination of pathological material, for even in infective conditions some of the lesions may be toxic (as in diphtheria) In the meantime the disorder needs a provisional name and "benign myalgic encephalomyelitis," although necessarily imperfect, has fewest disadvantages

To reiterate the main points, the following features appear early in the disease and should suggest this diagnosis

(1) Symptoms and signs of involvement of the brain and spinal cord

(2) Protracted muscular pain in chest abdomen or limbs, often with tenderness cramp, involuntary movements, spasm and paresis

(3) Normal cerebrospinal fluid

(4) A characteristic electromyogram

(5) Involvement, in some variants, of the reticuloendothelial system

Low or absent fever, protracted course, a tendency to relapse, and mental symptoms in convalescence are features of some cases A curious jerky response of the affected muscles to volition in convalescence may prove to be a further clinical characteristic of this fascinating disorder.

ÆTIOLOGY OF PRE-ECLAMPSIA

SIR,—An important point in considering Mr Sophian's views (March 9 and 16) is the question whether, in pregnancy (not necessarily the same conditions as those in Mr. Sophian's experiment when he demonstrated the uterorenal reflex) the growing volume of fœtus and membranes is in reality putting as high a pressure on the walls of the uterus as Mr Sophian assumes

Many obstetricians who have had to rupture the membranes of primiparæ who are not in labour have noted the fact that the bag of waters is very often not distended but shrivelled [1] The same thing has been found in twin pregnancy The intra uterine pressure in twin pregnancy is not increased.[1] In acute hydramnios a high intra-uterine pressure is obviously not primary but secondary to greater secretion of the amniotic fluid or to increased permeability of the vessels in the membranes

I find it hard to see how the intra-uterine pressure can be high during the whole of pregnancy The pregnant uterus is not distended by the growing fœtus (as for example, the finger of a rubber glove may be, by insufflating it and putting the contents under pressure), the muscle cells are multiplying continually, and in this way the walls of the uterus are trying to adapt themselves, by becoming longer, to the growing volume of fœtus and membranes, which are in no way exerting pressure upon the uterine walls

These walls are not overstretched and the lumina of their arteries not narrowed, the construction of these arteries (curling or corkscrew arteries of Hunter) is an extra safeguard against such events Hypertension in those arteries has never been demonstrated, but it is often said that, during pregnancy, conditions in them are the same as those under which Goldblatt demonstrated hypertension by applying a clamp to a renal artery Such assertions, however, are based on the assumption that in pregnancy the intra-uterine pressure is increased, but this assumption is not clearly proven

In adrenalectomised animals Goldblatt could not produce hypertension by applying a clamp Even admitting that in toxæmia of pregnancy (e g, in acute hydramnios) the contents of the uterus may now and then press upon its walls, in the way Mr Sophian does during his experiments obviously a situation of stress would be created and the adrenals might play an important part in producing the resulting symptoms—e g, by producing adrenaline and so constricting the renal cortical arteries The Trueta phenomenon is often observed after stress

Mr Sophian is obviously following Conn when he says that the hormones are playing only a secondary part during toxæmia of pregnancy But 2 of Conn's 5 patients were Negresses just recovered from severe toxæmia of pregnancy [2], and Conn's syndrome and aldosteronuria can be provoked in animals by implanting stilbœstrol crystals [2] or injecting growth hormone [3] For these reasons I am doubtful whether the distinction between primary and secondary aldosteronuria is a justifiable one

The study of Conn's syndrome, however, has made clear that

(1) The adrenal cortical hormones have a big influence on glomerular and tubular renal function, causing potassium loss, proteinuria, and sodium retention—symptoms which disappear when a cortical tumour is extirpated

[2] Franks L M, Chesterman, F C Lancet 1956 ii, 1193

[3] Moon, H D Koneff A A Li C H Simpson, M E Proc Soc exp Biol, N Y 1956, 93, 74

(2) These tumours often contain over 8000 µg of aldosterone[4] The quantity of aldosterone found in the urine daily in cases of primary and secondary aldosteronuria is of the order of 30–60 µg evidently the adrenal cortex is storing most of the aldosterone synthesised there, as the adrenal medulla stores most of the adrenaline and noradrenaline Only on special occasions is a little part of the store poured into the circulation Could this reaction be provoked by histamine, liberated after an antigen antibody reaction ?

The study of the urinary excretion of aldosterone, adrenaline, noradrenaline, and the so called catechol derivates, immediately before, during, or immediately after the eclamptic fits seems to me to be of prime interest for solving the question of the ætiology of toxæmia of pregnancy Recently Selye expressed the same view[5] The uterorenal reflex, curious as it may be, is to my opinion not an active factor in the pathogenesis of toxæmia of pregnancy

R SCHUURMANS

NEURONE SELECTION IN RELIEF OF PAIN

SIR,—Professor Lehoczky (Feb 16) refers to the use of 10 ml of 0 5% aqueous phenol injected into the first or second sacral foramen for sciatica and similar pain from other causes I have used this approach of Bonica[6] and endorse its value, and would in fact prefer it to intrathecal methods for non-malignant conditions

Pain from cancer, however, is a different proposition Here at the Pain Relief Centre we have to afford relief at any level ranging from the highest occipital to the lowest sacral segments To give some idea of how formidable this is, for cancer in the pelvis alone the segments which must be reached often extend from D11 to S3 or 4 Here, it is essential to eradicate systematically the small non medullated C fibres from some 11 to 12 roots for unilateral pain, and 15 or more for bilateral pain This number of roots can be influenced in bulk only by intrathecal injection using 1 ml phenol (1 in 20 in glycerin) at the D11–12 interspace, followed after five days by a similar 1 ml injection at the L4–5 interspace for one side Bonica's approach, though of value at the sacral sciatic site, could never be expected to cover this range of neurones often met in carcinoma After intrathecal injections, the rapidly acting phenol sometimes cannot penetrate at some of the roots and becomes inactivated, leaving pain residue at the corresponding sites This resistance is often due to sheltering of neurone cells by areas of carcinoma, as Dr Shrigley demonstrated for me

A slower acting agent, such as phenol and silver nitrate, allowed greater penetration before it was neutralised, and relieved half these resistant cases If such intrathecal methods were unsuccessful it was considered that the peripheral end of the ganglion might be reached For this purpose relief has often been completed by epidural injections at the resistant sites Bonica's method might be defined as epidural injection with the advantage of presenting a bulk of solution to the nerve-roots close to the ganglia This proximity to the ganglia is essential, otherwise gasserian-ganglion injection would not be required for 5th-nerve pain Ordinary epidural injections unfortunately tend to follow the diffuse outline shown in the first radiograph in my article (Jan 5) This has been partly overcome by collapsing the dural sac by puncture at a different level to drain the C S F, followed by an epidural injection further down, with the "draining" needle left in situ The patient lies on the pain affected side

I would therefore say that for pelvic carcinoma the neurone elements must be influenced in length—i e, from D11 to S1 or 2—and in depth, so that the ganglion cells are influenced throughout Recently I have added Bonica's method in some of my cases, and it has been of great value for providing penetration from the peripheral site in the locality where subarachnoid penetration was insufficient

Rochdale

R M MAHER

A STUDY OF WAKE

SIR,—Surely Dr Jacobides's definition of sleep (March 30) rests on the unwarranted assumption that the starting point for all thought about sleep wake is unquestionably and of necessity wake, not sleep It is this assumption that seems to me to be so wrong It is like a physiologist trying to study muscle action by assuming that the experiment begins with a contracted muscle, or like an educationist looking at a senior wrangler and wondering how such a person could ever have been in a state of not knowing his twice times table It is starting thought from the wrong end

One is surely justified in seeking an understanding of the problem from as far back in life as possible It is Barcroft himself who uses the words "asleep" and "wake" in describing fœtal behaviour

I quite agree with Dr Jacobides that the concept of "wake maintainers" may not appear convincing at first sight, and it is here that research is most necessary, especially in the earliest manifestations of wake maintenance in young babies Why does the reticular activating system sometimes "keep open" for a time after the original arousal stimulus has subsided, especially if the wake maintainer appears to be a simple, innocuous, and unvarying stimulus ?

Perfect sleep is certainly biological "well being," but this is not to deny that wake may be "better becoming" !

W. V CRUDEN

INSULIN TREATMENT OF SCHIZOPHRENIA

SIR,—Sacred cows are hardy animals, and the insulin coma treatment illustrates this too well It never was any good, but mental hospital doctors found relief in being high powered therapists of schizophrenia instead of the mere custodians they once were, so its legendary reputation thrived There were adverse studies, but they were lost amid an enthusiastic deluge and, for 20 years, the method lived on without a single comprehensive review in the language really to challenge it Ultimately, when I came to supply one in your columns,[1] the average psychiatrist was seldom any longer aware that strong doubts had always existed about insulin, and in some respectable quarters too

Heresies are not immediately popular, and the heated correspondence that ensued was largely as expected There has been no pause in expenditure on new insulin coma units, they have remained a priority, and even in poor, under developed countries, experts from Britain still have not hesitated to advise the immense investment they entail

However, there were signs of a turn in the tide Whereas only a bare dozen studies questioning, in one way or another, the value of insulin coma appeared over the whole 20 years preceding my review, at least seven have been published since[2–8] And now, surely, the report by Dr Ackner and his colleagues (March 23) must at last compel a change in prevailing policies Here we finally have the most carefully arranged trial on record, and it confirms that the treatment has no specific value, and none, moreover, in the very type of case where its use is particularly recommended

The purpose of this letter is to suggest that the continued use of insulin-coma therapy has not only become irrational but is an actual menace to the mentally sick Being wildly extravagant in the scarcest of mental-hospital commodities—namely, money, and medical and nursing time—it beggars other provision, it has a mortality which is not negligible, and, worst of all, it effectively screens doctor and patient from any other approach to the problems of schizophrenia The psychiatrist in training probably suffers most damage Juniors are usually posted in the insulin unit, thus, at its foundations, their knowledge of schizophrenia includes no subtle observation of its psychology and no experience of psychotherapy Insulin coma therapy even impedes the proper use of electroconvulsive therapy, which is learnt as a casual procedure, administered sporadically and without system, as an adjuvant to the insulin ritual

No doubt the insulin treatment will be defended to the death The "it can't do-any-harm-to-try" argument is not only destitute, it is false and dangerous

HAROLD BOURNE

UTERINE ELECTROLYTES IN PREGNANCY AND LABOUR

SIR,—We were most interested to read the account of changes in uterine electrolytes in pregnancy and labour given by Dr Cort and Dr Cort (April 6), since we have been working on this and related problems for the past two years A preliminary note of certain of our findings has already appeared [1]

It is implied in the Corts' paper that hysterectomy specimens, from women under 46 years of age, represent normal uterus We feel that this assumption is probably unjustified To illustrate this point, table I shows a comparison between the electrolyte composition of normal myometrium (biopsies taken at mid-cycle during plastic and other operations on the uterus) and myometrium from uteri which contained fibromyomata The specimens from fibroid bearing uteri are divided into two groups—those in which one or more seedling fibroids were present and those in which a hysterectomy had been performed for multiple fibroids It will be noted that the changes in electrolyte pattern are more extreme in the second group We have some evidence that these changes are due to hyperœstrinism Electrolyte disturbance in the uterus appears to occur also in other disorders necessitating hysterectomy Further, Daniel and Boyes [2] have found some evidence of changes in uterine electrolyte pattern during prolonged bleeding necessitating hysterectomy

TABLE I—INTRACELLULAR IONS IN HUMAN MYOMETRIUM

—	Normal uterus	Fibromyomata present	
		Seedlings	Multiple fibroids
Intracellular K+ (m eq per 100 g dry)	28	31	27
Intracellular Na+ (m eq per 100 g dry)	1	4	6
K+ concentration (m eq per kg intracellular H_2O)	122	107	90
Na+ concentration (m eq per kg intracellular H_2O)	9	13	19

Dr Cort lays some stress on his finding of a progressive loss of potassium from the myometrial cells during normal pregnancy and labour Our figures do not entirely support this contention (table II) We were unable to detect statistically any actual loss of potassium from the cells as a consequence of pregnancy or normal labour, though the total intracellular potassium levels did fall in inert labour There was a fall in the calculated concentration of potassium in the intracellular fluid of the myometrial cells during normal pregnancy and labour (table II) This appeared to be due to increased hydration of the cells Our values for intracellular sodium, which is elevated in pregnancy, are probably comparable to those of the Corts though the actual figures differ because a slightly different assumption was used in determining extracellular space The values in pregnancy and labour in table II refer to the lower uterine segment, as do those of Dr Cort We have, in fact, found parallel changes in biopsies from the upper part of the uterus

TABLE II—INTRACELLULAR IONS IN HUMAN MYOMETRIUM IN PREGNANCY

—	Normal uterus	Early pregnancy	At term		Delay in labour	
			Not in labour	In labour	(a) Early	(b) Late
Intracellular K+ (m eq per 100 g dry)	28	32	34	30	27	25
Intracellular Na+ (m eq per 100 g dry)	1	6	12	10	9	10
K+ concentration (m eq per kg (intracellular H_2O)	122	99	95	103	87	79
Na+ concentration (m eq per kg intracellular H_2O)	9	18	35	25	27	31

The cases of uterine inertia we studied were divided into two groups (*a*) where there was delay in dilatation of the cervix in the first 24 hours of labour (cases of failed trial of labour), and (*b*) where labour was in fact prolonged for more than 48 hours, and cæsarean section had to be conducted for delay where the cervix was more than half dilated In both these groups there was evidence of depletion of intracellular potassium, the values being most markedly reduced in group (*b*)

We feel that while the potassium concentration in the myometrial cells is reduced during normal pregnancy and labour, this is probably a physiological phenomenon due to hormonal conditioning and water retention rather than to a process of depletion or deficiency When our values obtained from biopsies of myometrium at hysterotomy in early pregnancy are compared with those at term and in normal labour (table II) there is no evidence of progressive change in intracellular potassium The reason why Dr Cort and Dr Cort find potassium reduction in their group of "normal" labours may be the incorporation in this group of cases of failed trial of labour and failure of the head to engage, with their implication of uterine inertia Such cases (table II, delay in labour, early) do have much reduced intracellular potassium We could find no such depletion in our biopsy specimens from patients in normal labour—cases who had been scheduled for elective cæsarean section but had gone into labour, and cases of fœtal distress, where there was no evidence whatsoever of incoordinate uterine action

In conclusion, therefore, we feel that there is no clear evidence that the changes in uterine electrolytes occurring during normal pregnancy and labour are other than physiological, or that the reduction in intracellular potassium that occurs can be regarded as a deficiency These changes may well be the consequence of changed hormonal influence—Talbot et al,[3] and Horvath [4] have shown that hormonal changes can influence the uterine electrolyte balance We fully agree with Dr Cort and Dr Cort that in uterine inertia there is a deficiency of potassium in the myometrial cells We have shown, in fact, in another study,[5] that plasma-potassium also falls in long labour—an effect we attributed to prolonged hypersecretion by the adrenal cortex This intra- and extra cellular potassium depletion may well contribute to the uterine inertia

HEAD INJURIES

SIR —The letters of Mr Lowden (Jan 12) and Professor McConnell (March 2) prompt me, albeit with some diffidence, to offer yet another solution to the problem of acute extradural hæmorrhage occurring at a distance from a neurosurgical centre

Twice in the past three years I have been faced with this problem The first patient, a child of three years, was 150 miles distant and the second, a youth of 17, was over 200 miles away In each case the classical signs of extradural hæmorrhage, including coma, had supervened within three hours of an apparently trivial head injury Air-transport to this centre was arranged, but, because even this method of transfer was not likely to prove rapid enough in view of the early onset of coma, the referring physician was advised to make a burr-hole in the appropriate temporal fossa and pack the wound open while awaiting the arrival of the air ambulance (In the first case the burr-hole was actually made with an ordinary brace and bit obtained from the local ironmonger) Both patients arrived with somewhat bloody dressings but otherwise in sufficiently good condition to make excellent recoveries following evacuation of their extradural hæmatomas

CLEARANCE RESULTS IN OLIGURIA

SIR,—Phillips et al[6] stated that division of the clearance for any substance by the intrarenal plasma extraction of the same substance gives the value for renal plasma flow (R P F $= \frac{C}{E}$) Consequently the R P F multiplied by the E for any substance will give the clearance for that substance ($C =$ R P F $\times E$)

In the dog dehydrated by thirsting we determined R P F by measuring directly the blood flow from the renal vein and the inulin, creatinine, and P A H extraction by analysing arterial and renal venous blood The clearance of these substances was also determined We found, that, below a diuresis level of 0 35 ml per min per sq m (i e, in oliguria) the value of $\frac{C}{E}$ is but a fraction of the directly measured value As extraction (E) is normal in oliguria, the low $\frac{C}{E}$ value can be ascribed to a misleadingly low clearance value only On enhancing diuresis by mannitol or saline infusion the difference between the direct value and $\frac{C}{E}$ disappears inasmuch as R P F and F change very little, but the clearances increase to their true value

This finding has placed in a different light Chesley's statement[7] that in man the urinary concentration of different substances does not change below a diuresis value of 0 35 ml per min, and in that range the value of clearance is proportionate with that of urine output Our data indicate that in extreme oliguria the regulation of diuresis does not become a glomerular function, but the clearance values are unreliable We believe that in oliguria, even in clinical practice, one should be very cautious in evaluating clearance results

A detailed account of our data is to be published in *Acta physiologica hungarica*

Physiological Institute,
University of Budapest

RHEUMATOID ARTHRITIS WITH CHRONIC LEG ULCERATION

SIR,—In their courteous reply of March 30, Dr Allison and Dr Ray Bettley have paid but scant attention to what they themselves agree is the crux of their whole argument—namely, that in their cases they could apparently rule out any question of venous stasis because the ulcers failed to heal in bed

To say "we need hardly detail the bed rest and ancillary treatment" is to present statistics without figures, for if bed rest is not completely and accurately controlled in these patients it may quite well *appear* to be worse than useless

Many with stasis ulcers give a history of these failing to heal despite prolonged "bed rest" Fortunately most of them can be healed by elastic adhesive ambulatory compression, but in the very difficult cases that we are discussing, in which ambulation is reduced to a painful and pitiful minimum, bed rest will invariably do the trick provided the patient *lies down* (twenty four hours a day, except for meals and their excretion) *in a bed tilted nine inches at the foot*

My impression is that the Middlesex cases were *not* so treated, and I must emphasise once again that until this has been tried there is positively no evidence on which vascular stasis can be excluded as an ætiological factor

London, W 1

STANLEY RIVLIN

SIR,—Like Dr Rivlin, I fear that Dr Allison and Dr Ray Bettley's conclusions (Feb 9) are not quite justifiable I had the opportunity to treat 3 patients similar to those they cite, and I report here the history of 1 who is still under my care

Six years ago a housewife aged 50 first had symptoms of rheumatoid arthritis which steadily increased in severity and caused much deformity Three years ago many cutaneous nodules began to appear over the elbows and the backs of the thighs From time to time one or two nodules broke down and punched out ulcers were formed which healed rather easily She ran a fever for a long time, with spikes as high as 39°C (102°F) In the past skin eruptions had very often been controlled with anti histamine drugs

Fifteen months ago she was further crippled by a big ulcer on the outer surface of the lower third of the right leg The ulcer appeared on the fifth day of a course of treatment with cortisone, which was therefore stopped Previous treatment of the arthritis included courses of gold, salicylates, phenyl butazone, and iodides The ulcer healed very slowly, probably because she was not strictly confined to bed When bed rest was ordered with the leg raised above the level of the heart, after three months it was completely healed

Apparently the ulcer resulted from vascular stasis caused by the restricted muscular activity in the leg Interstitial œdema and decreased tissue resistance induced by cortisone may also have played a minor part

It is hard to accept the diagnosis of lupus erythematosus in the cases described by Dr Allison and Dr Ray Bettley Not only leg ulcers but also true allergic manifestations (skin eruption, drug sensitivity, and sometimes bronchial asthma) are quite common in rheumatoid arthritis Surely not all these patients have disseminated lupus erythematosus It would be better perhaps to put all these patients into the category of rheumatoid arthritis with collagenous manifestations

PHENYLBUTAZONE IN SUPERFICIAL PHLEBITIS

SIR,—Dr Gillhespy's observation (April 6) on the therapeutic effect of phenylbutazone in superficial phlebitis could be explained by its anticoagulant action, investigated and described by Humble.[1]

If in fact this is the correct explanation, phenylbutazone might not offer any advantage over the established anticoagulants, since its effect in this respect would appear to be variable and unpredictable.

Twickenham, Middlesex   DAVID WHEATLEY

EMULSIFIERS AND CORONARY THROMBOSIS

SIR,—Much has been published in the daily press lately on the increase in the number of cases of coronary thrombosis, the main suspicion being directed at the amount of animal fat consumed by the class of person most likely to be afflicted.

May I, just a layman, point a finger of suspicion at certain substances which are being used in ever-increasing quantities in many of the common items of food more than likely to be eaten by the same class of persons.

I refer to glyceryl monostearate and other emulsifiers which enable fats to be mixed easily with water, and I would suggest that when they are consumed in the diet in large quantities they may be absorbed and alter the state of the fat in the blood and so possibly be responsible for the damage to the arteries and cause thrombosis.

Taking this matter a step further, the use of detergents, which are also emulsifiers, for washing up crockery, and which are not properly rinsed off, can introduce into the digestive organs another substance which may alter the state of the fat in the blood.

Glyceryl monostearate is used as a crumb softener in much of today's bread, in ice-cream to increase the bulk or volume from a given weight of fat, in cake mixes to enable the house-wife to make quicker cakes, and in prepacked cakes which remain soft for many days.

I think investigations along these lines might prove very profitable, although I must confess I send this letter with trepidation.

Bristol 4   F. J. ROBERTS

FRACTURES OF THE FEMORAL NECK

SIR,—Mr Newman (March 30) paid a generous tribute to a factual review by Dr Murray and Mr Young (March 23) of fractures of the neck of the femur treated at the Southern General Hospital, Glasgow. He noted a high mortality rate and, while accepting the likelihood of error in any statistical comparison, suggested that this was evidence against delay in operation.

As an illustration that we are dealing here with a particularly poor-risk group, it should be said that some of our cases have been discharged home from other city hospitals as being unfit for surgery and thence admitted to our wards by the Beds Bureau. The high mortality quoted (33% overall, 26% for operative cases, and 48% for those treated conservatively) is also a measure of the difficulties of disposing of geriatric cases from acute surgical wards.

Mr Newman compared this with an average mortality of 16.8% among 564 patients treated surgically, collected from the literature. The mortality-rate for our 139 patients treated surgically *was 14% in the first twenty-eight days*.

This would surely provide a fairer figure for comparison, since as far as American publications are concerned at least, it is rare for a bed in an American hospital to be occupied by the same patient for twenty-eight days. Few of our patients went home within twelve weeks.

Certainly if we are to compare the results of immediate operation (within twenty-four hours) with those of elective operation (average time from fracture till operation, four days) surely the mortality-rate in the first month is the figure to take.

Southern General Hospital, Glasgow, S.W.1   W. SILLAR

CYTOLOGICAL DETECTION OF UTERINE CANCER

SIR,—Dr Anderson (April 6, p. 738) is quite correct when he states clearly that cytology is no longer an untried method in the research stage, but in the Birmingham study[1] of the value of cytology in gynæcological practice which we carried out at the request of the Royal College of Obstetricians and Gynæcologists, the establishment of the technique in the hands of technicians (none of whom is medically qualified) amounted to research.

First of all we had to show that in our hands the technique would confirm the presence of obvious cancer of the cervix, which was soon established. A lower efficiency, however, was inevitable in cancer of the corpus, for cells are not shed regularly or may be swamped with blood. The most important part of our research, however, was to find out for ourselves how many cases of cancer we were missing in routine investigation of outpatients. To keep our clinical practice up to a high standard we used a questionnaire and we inspected the cervix with great care. Since 1954 we have abandoned the detailed questionnaire and simply write down on our case sheets in the outpatient department that this patient has or has not carcinoma of the corpus or cervix. We are thus tied down as clinicians, leaving the cytologist a chance to claim a "pick-up" for the technique, should cancer cells be obtained from a clinically normal case.

How many cases were we missing, for obviously 1 per 10,000 would have made the technique valueless, whereas 2% would have made it almost obligatory for our or for any gynæcological clinic? We found that in 2250 patients (in two years) we had missed 1 case of early cancer of the cervix. We also missed 1 case of carcinoma of the corpus which escaped our exploratory curette, but the risk to her life was less in that postmenopausal bleeding would have made hysterectomy obligatory without positive smears.

Our conclusion was therefore that, in our practice, cytology was almost never required to reach a diagnosis of uterine carcinoma. But cytology led us to discover 8 examples of carcinoma-in situ which would have escaped our usual investigations. We have now screened over 5000 patients and the figure of 3 per 1000 is being maintained. With many hundreds of hours of microscopy was this a reasonable "harvest"? We concluded that it was, and in this came into line with many centres in the U.S.A. and elsewhere, including this country.

M. J. D. Noble and M. E. Attwood have applied this "search" technique to diabetics (Dr J. M. Malin's patients) and this study is ready for publication. Their "harvest" is greater than in our outpatients, not only for invasive but also for "in situ" lesions.

Studies are also continuing in the field of therapy; for instance, 13 of our cases of carcinoma-in situ have been "treated" simply by deep ring biopsies—i.e., we have the beginnings of information on therapy.

Dr Anderson suggests that although cytology per se is not research the technique can be used as part of research into the natural history of cancer. I suggest that the operative word "can" should be replaced by "must"; but in this my colleague, Dr C. W. Taylor, director of pathology, Birmingham Hospital for Women, does not entirely agree with me. My opinion is based not simply on the fact that it takes hundreds of hours of microscopy to discover 1 case of carcinoma-in situ but that each case should be a subject of study to offset the time-consuming work by the cytologist.

---

[1] Humble, J. G. Empire Rheumatism Council Symposium on Butazolidin, Nov. 13, 1953.

[1] McLaren, H. C., Taylor, C. W., Attwood, M. E. J. Obstet. Gynæc., Brit. Emp. 1956, 63, 801.

In our own firm, ordinary clinical study involves the automatic admission of all patients with positive smears for ring biopsy and curettage, this is followed by long-term follow-up studies by the clinicians and cytologists and, of course, a complete study of the histology may require us to undertake radical surgery In other words, we are recording facts which may be of use to us when presented with therapeutic problems—e g, the woman of 28 with carcinoma-in situ who wishes to have a family

I believe further that the time has now come to carry out what Malcolm Donaldson proposed in 1951—namely, that our findings and our results should be centralised in a "British committee for the study of carcinoma-in-situ" The condition is rare so that individual centres in Worcester, Derby, Glasgow, Newcastle, Liverpool, Manchester, Oxford, and London, where cytologists are at work, are unlikely to find sufficient cases or to study them long enough to give us within a reasonable time some knowledge to guide us in therapeutic problems Therapy, of course, is based on a knowledge of the natural history of carcinoma in situ

To sum up, then, I agree with Dr Anderson that cytology is not per se research but offers a challenge to those who employ this most tedious and time consuming test not to be content with a "routine service" but to write up every case with care, and to include prolonged follow-up irrespective of the therapy employed An appeal is also made for an extension of the work at present centred in the Royal College of Obstetricians to include all centres willing to take part in a joint effort to increase our knowledge of what is a most interesting and ill-understood condition—carcinoma-in-situ

Queen Elizabeth Hospital,
Birmingham, 15 **H C McLAREN**

SIR,—Your leading article of March 23 surprised me by its arguments Some 15 years after the introduction of cytology into gynæcology, at a time when cytology has not only been fully recognised and established as a diagnostic method in the United States but is already represented by regional professors of the specialty, we are still asking in Britain, "is cytology really necessary?"

There should no longer be any doubt that cytology can detect cancer cells in vaginal secretions, that these cancer cells may come from the vagina, cervix, endocervix, body of the uterus, or, occasionally, from the ovaries, and that clinically unsuspected malignancies (be it that the lesion is microscopical or outside the reach of the inspecting eye) are recognised at a stage when other methods fail There is equally no doubt that cytology does not provide a 100% guarantee of a correct diagnosis No laboratory method is infallible there are as many pitfalls in biopsy techniques, and anyone who expects that the laboratory can replace clinical judgment lives in a fool's paradise

Is it really of paramount importance which figure of "pick up rate" (Anderson's 1 1% or McLaren's 0 44%) is more accurate, and do you really think the fate of cytology should depend on this assessment? "Pick up rates" vary according to the material screened, and depend also to a large extent on the clinical acumen of the gynæcologist as well as on the skill and experience of the cytologist All these points are variables and it is, therefore, not surprising that different figures are quoted in the literature It might be wise if, before discussing "the true value of cytology," we first found a definition of what constitutes a cytologist It appears that judgment on the value of cytological investigation is often passed by people who have been toying with the technique for a short while and, for lack of competition in this field, feel entitled to regard themselves as authorities

Early cancer detection is but one aspect of the method and there are others Vaginal cytology offers useful and reliable information on ovarian function during the reproductive period and provides important help in the decision as to what type of hormonal treatment should be used in menopausal disturbances Lastly, it plays a unique rôle in cancer follow-up examinations as a detector of early recurrence or failure of response to treatment

May I finally make a plea for cytology? Do not let us lose our sense of proportion when evaluating a new method by demanding the impossible Do not let us forget that the vaginal-smear technique is just one way of examining a patient, widening the field of diagnostic possibilities, and should be used in addition to but not instead of the other time-honoured methods We argue about a failure rate of approximately 10%, but do not let us forget that there are still 90% of patients who benefit by the method

Institute of Obstetrics and Gynæcology,
Hammersmith Hospital, London W 12 **ERICA WACHTEL**

HASHIMOTO'S THYROIDITIS

SIR,—Two recent papers[1] in which Hashimoto's thyroiditis or struma lymphomatosa are mentioned in the titles raise an important question When dealing with a condition which is not an everyday matter, it is, I think, necessary to define it beyond a perfunctory "histological sections showed the typical appearances of Hashimoto's thyroiditis," with or without the name of the doctor diagnosing the material It has been my own experience[2] that too often what is commonly referred to as "Hashimoto's struma" is not what Hashimoto[3] described, but what appears in textbooks, which, as I recall Gooch's remark about history texts that one is a copy of the other plus the spice of original error, is usually erroneous May I suggest that a brief summary of diagnostic criteria be included in any paper which seeks to discuss the less common pathological states

Los Angeles **S M RABSON**

GOVERNMENT AND PROFESSION

SIR,—I read with great interest Dr Fry's letter (March 30) and should like to support and reinforce much of what he says

If a Royal Commission is to sit on doctors' remuneration, then the terms of reference should be so wide that the whole system of remuneration of general practitioners will be brought under review, and for this purpose doctors should be added to the existing lay members

Is it not long past time to change a system which penalises the good doctor, which can pay to the experienced clinician the same emoluments as to his youngest colleague, and which offers as the only inducement to the keen and able doctor, if he wants a good reward, the compilation of a big list, with no hope of easing up until he retires?

What is the alternative? What method could be introduced which would encourage good practice only, which would offer incentive to the young, and some relief to those getting on in years? Here I break away from Dr Fry and put forward my own proposals

The general practitioner's income in future should be made up as follows

(a) An expense factor —This would very broadly cover his practice expenses as allowed for income tax purposes, thus giving the doctor every day as he starts the day's work a tranquil mind, without having to think "Have I got enough heads to live?"

(b) A length-of-service factor, as in other Government medical appointments

(c) Awards for special skills or a very high level of service

(d) Locality allowance, to be paid to doctors who practice in specially difficult areas or in resorts largely inhabited by old people

---

[1] Luxton, R W *Lancet* March 2 1957 p 441 Morgans, M E Trotter W R *Ibid*, March 16, 1957, p 553
[2] Rabson S M Arata J E *Amer J clin Path* 1949, 19, 751
[3] Hashimoto H *Arch klin Chir* 1912, 97, 219

(c) A capitation fee, uniform throughout the country, to be paid for each patient

This method would encourage good practice, reward experience, and console those who work in difficult areas

Worthing HAROLD LEESON.

TRAINING IN ADMINISTRATION

SIR,—Your readers will notice in your advertisement columns this week that the Newcastle Regional Hospital Board are advertising for an administrative medical officer, that no administrative experience is called for, and that a clause is used saying that facilities for training will be offered. May I enlarge on this advertisement for what is essentially a trainee appointment ?

" No concerted action has, to the best of my knowledge, been taken in this country to train medical administrators, and the Newcastle board are hoping to do something of a pioneer nature It is hoped that applications will be forthcoming from those whose experience is solely clinical or solely in public health , if such a candidate is appointed to the post, a planned programme of training will be undertaken, including attendance at suitable courses and secondment to general, special, and mental hospitals for varying periods Very probably the doctor appointed will also be "lent out ' for periods of perhaps a week at a time to one or two hospital management committee group centres in order to see the work at this level Should the doctor appointed wish to take a higher qualification, full facilities for this will be offered , should he wish to take the D.P.H examination of the University of Durham suitable time off will be given in order to allow this

R H M STEWART
Senior Administrative
Medical Officer

Newcastle Regional Hospital Board

SHERRINGTON CENTENARY

SIR,—This is the centenary year of the birth of Sir Charles Scott Sherrington. O M , a founder and main architect of the physiology of the nervous system The Royal Society of Medicine, wishing to pay tribute to his life and work, proposes to raise a fund towards a Sherrington lecture, for the furtherance of knowledge on the nervous system, to be delivered from time to time in the society's rooms in London It is felt that many will wish to contribute both those who were his friends pupils, and colleagues, and those, more numerous, who, as patients doctors, and scientists, have benefited indirectly from his work. We wish to take this opportunity to commend the endeavour of the Royal Society of Medicine to establish this memorial to a great pioneer in scientific medicine.

Donations should be made payable to the secretary, the Royal Society of Medicine, 1, Wimpole Street, London W 1, and cheques crossed " Sherrington Memorial.

Medicine and the Law

Shortening of Life

THE trial of Dr John Bodkin Adams on a charge of murdering a patient by administering drugs has been reported at great length in the national press, and there is no need to review here the course of the longest murder trial in English history and one which ended in the acquittal of the accused But the judge's summing-up, which lasted for four hours, contained some important remarks on the position of a doctor after health can no longer be restored to a patient

Mr Justice Devlin began by emphasising a point which is familiar enough to the medical profession—namely, that no one has the right deliberately to cut off life Murder, he said, was " an act or series of acts done by the prisoner which were intended to kill and did in fact kill." It did not matter for this purpose that death was inevitable If life were cut short by weeks or months, it was just as much murder as if it were cut short by years The jury, said his Lordship, had heard a good deal of discussion about the circumstances in which doctors might be justified in administering drugs which would shorten life—cases of severe pain had been suggested and also cases of helpless misery. "The law knows of no special defence of this category."

His Lordship went on to say, however that this did not mean that a doctor aiding the sick or dying had to calculate in minutes or hours or perhaps in days or weeks the effect on the patient s life of the medicines he administers " If the first purpose of medicine—the restoration of health—can no longer be achieved, there is much for the doctor to do, and he is entitled to do all that is proper and necessary to relieve pain and suffering, even if measures he takes may incidentally shorten life '

The judge was careful to explain what this last statement meant

It is not the case that there is any special defence for the medical man and it is not the case that doctors are put into any different category to other citizens What I have said rests merely upon this part of the offence of murder, that no act is murder which does not cause death—and ' cause ' means nothing technical or scientific it means what you twelve men and women sitting as a jury in the jury-box would regard in a common sense way as the cause

" Manifestly, there must be cases in the hospitals day after day in which a doctor is faced by whether giving certain treatment or omitting to give certain treatment prolongs or shortens life by hours and perhaps even longer

" The doctor who decides to administer a drug, or not to administer a drug is not of course thinking in terms of hours and minutes of life He could not do his job properly if he were

" If for example a doctor has done something or omitted to do something and death occurs say on the 11th or 12th or on the Monday instead of the Tuesday, no one with commonsense would say the doctor caused the death.

" They would say the cause of death was the injury or whatever it was that brought her to hospital It remains a fact and remains the law that no doctor, nor any man has the right to deliberately cut off life I say it to you so there can be no mistake

" It does not enter into the defence at all No defence has been put forward that has vested any right in Dr Adams to make this determination in this case or any other case

' Counsel for the defence is saying that treatment given by Dr Adams was treatment designed to promote comfort, and if it be the right and proper treatment the fact if it be that it shortens life does not convict him of murder ' [1]

In concluding this part of his summing up, Mr Justice Devlin referred to the use of the word " justify " in relation to a course of treatment It was, he said, a pity that the word had ever been brought into the case To the lawyer it suggested some legal justification

" In this case the word ' justify ' was used purely in the medical sense If a doctor is going to prescribe a course of drugs we have heard the sort of dangers that may result

' The patient may become comatose and the effect on the patient may be a complication, pulmonary congestion and so forth and it may lead to death. and therefore the doctor who is going to prescribe this treatment has to consider that and has to ask himself whether he is justified in a medical way in running that risk

---

[1] *Evening Standard*, April 8 1957

"The word 'justify,' as I understand it, has been used purely in that way Dr Ashby has said there was no such dreadful discomfort as would justify the administration of those drugs, and he is saying simply the risks that were being run by administering those drugs were not justified"

Permanent and Pensionable

A woman clerical worker sought in the Chancery Division and the Court of Appeal of Northern Ireland a declaration that her engagement under the Northern Ireland General Health Services Board had not been validly terminated, and eventually appealed to the House of Lords against decisions in favour of the board The House of Lords by a majority (Lord **Tucker** and Lord **Keith** of **Avonholm** dissenting) allowed her appeal.

In June, 1948, when unmarried, she applied for a post as senior clerk under the board The post was advertised in a Belfast newspaper and the advertisement stated that "subject to a probationary period appointments will be permanent and pensionable" She was selected for appointment, resigned from her previous employment, and started work on a six-month probationary period in August, 1948 Shortly after starting work, she was handed a document containing the full conditions of service They included the following clause

> 'Dismissal and reduction in rank, and termination of employment otherwise The Board may dismiss any officer for gross misconduct and may dismiss any officer who is proved to their satisfaction to be inefficient and unfit to merit continued employment Except where an officer has been guilty of gross misconduct, the Board shall give at least one month's notice of their intention to exercise their powers of dismissal under this rule As an alternative to dismissal, the Board may order the reduction in rank of an officer who is found by them to be unfit to discharge the duties of the grade in which he has been employed One month's notice in writing shall be given by all permanent officers who wish to terminate their employment with the Board"

In February, 1949, having served her probationary period, she was confirmed in her post On Aug 14, 1950, the board inserted in the conditions of employment a condition that "female officers will on marriage be required to tender their resignations to the Board" After being advised that that condition did not apply to officers already on the staff, she got married in March, 1951 The board thereafter sought to determine her employment by notice expiring in August, 1954

In the House of Lords Lord **Oaksey** said that the question depended on the construction of the contract The board had contended that in the case of a general hiring for an indefinite time a master was entitled to give his servant reasonable notice and that the contract in question was one of master and servant for a general hiring In his Lordship's opinion this was not a simple contract of general hiring for an indefinite time It began by an offer of a permanent and pensionable post, and the contract incorporated provisions that the officer was entitled to an annual pension on a contributory basis on completing 10 years' service in circumstances of ill health or on attaining the age of 60, a short-service gratuity for 5 years, and other pension rights and allowances for sickness To offer an officer a permanent and pensionable post on such terms and then to claim the right to give him notice which would deprive him of all the pension and other rights offered by the express terms of the contract not only was not a right which the parties must have intended the master to have but one which no reasonable person could have contemplated he would claim The appeal should be allowed

Lord **Goddard**, concurring, said that, while he did not think that because a person was offered pensionable employment the employer thereby necessarily engaged to retain the employee in his service long enough to enable him to earn a pension, nevertheless when one considered the express condition here relating to dismissal the fact that the offer in the advertisement was for permanent and pensionable employment assisted in construing it On the true construction of clause 12 the board had debarred themselves from giving notice apart from the reasons specified therein

Lord **Tucker**, dissenting, said that the natural meaning of the words "permanent and pensionable" in their context in the advertisement indicated no more than that the posts available were on the regular established staff and were subject to the terms of a pension scheme The advertisement formed no part of the eventual contract The appellant could not reasonably have supposed that the final terms of her contract would give her the legal right to a life appointment

Lord **Keith** of **Avonholm**, also dissenting, said that the case might have repercussions on the powers of public bodies or authorities which did not rank as branches of the Civil Service to terminate the employment of their servants If the appellant succeeded the position would be the more remarkable in that it would be only the board that was bound, for the servant was entitled to terminate her employment at one month's notice

Lord **Evershed**, who concurred with the majority of the House, said that the result of the decision might be to saddle the board with contracts which they ought not reasonably to have undertaken, but to a servant, certainly one in the position of the appellant, the security of employment with the board for the period of working life was of immense value

McClelland v Northern Ireland General Health Services Board *House of Lords* (Lord Oaksey, Lord Goddard Lord Tucker Lord Keith of Avonholm, and Lord Evershed) April 4 1957 E W Jones Q C, and C B Shaw (Gouldens for J Morris McKee, Belfast), W F Patton, Q C, and John MacDermott (Hewlett & Co for Cleaver, Fulton & Rankin, Belfast)

M M **Hill**
Barrister at-Law

Allegations Withdrawn

Allegations of negligence against a casualty-officer were withdrawn after a hearing at Birmingham Assizes[1] A widow claimed damages for the death of her husband in Nuneaton Manor Hospital from the casualty officer and the Birmingham Regional Hospital Board

Her husband, who was 39, was taken to hospital by his family doctor because he was having difficulty in breathing The doctor told the casualty officer that, in her view, the patient had "an acute condition of the larynx" and would probably need a tracheotomy She impressed on him that it was a serious emergency and then left the hospital Counsel for the plaintiff said that though suing both defendants, from what the hospital had told him he was putting his case "fairly and squarely" against the casualty officer, and he spoke of a "deplorable state of inefficiency and panic" When the patient's wife arrived at the hospital, no one was able to tell her anything Later she was taken to the matron's office, where another doctor broke the news to her that her husband had died

In evidence the patient's family doctor said that when she heard the man had died she asked the casualty officer why "on earth" he had not attempted the tracheotomy He replied that there had not been time

Counsel for the casualty officer denied that his client had done "simply nothing" when the patient was brought in. He had done everything possible before he tried to get in touch with an ear, nose, and throat surgeon In his evidence, the casualty officer said that on the day in question his immediate superior and two other doctors were away When the patient was brought in he ordered an injection and telephoned a surgeon, who told him not to do the operation until told to do so by the surgeon on duty He was unable to contact the surgeon on-duty and while he was telephoning the first surgeon to say he intended to operate, he was told the patient had died

A consultant ear, nose, and throat surgeon gave evidence that a hurried tracheotomy was often very difficult "even to an expert" Counsel for the plaintiff announced that, in the light of this surgeon's evidence, it would not be right to proceed with the allegations of negligence The plaintiff recognised that the casualty officer had been faced with a most difficult dilemma

Counsel for the casualty-officer said that facts which had been clearly established at the hearing were not known to the plaintiff at the beginning of the case, and Mr Justice Pearce, agreeing to withdraw the record, said it was clear the patient was suffering from a rare disease which was very difficult to diagnose and treat

Obituary

GEORGE RITCHIE MATHER CORDINER

C V O , M B St. And , D M R E

Dr Mather Cordiner, honorary radiologist to St George's Hospital, died at his home in London on April 8 at the age of 58

He graduated M B from the University of St Andrews in 1922, and after holding a house-appointment at Gravesend Hospital he served as a clinical assistant in the X-ray and electrical departments of the Prince of Wales's Hospital, Tottenham In 1924 he took the D M R E , and soon afterwards he became assistant radiologist to the Middlesex Hospital He also joined the staffs of the Evelina Hospital, St Paul s Hospital, the Royal Northern Hospital, and Oldchurch Hospital Romford In 1935 he was appointed assistant radiologist and later radiologist to St George's Hospital and after the introduction of the National Health Service he continued to serve the hospital as an honorary consultant He lectured in radiology at the London School of Hygiene and Tropical Medicine

Dr Cordiner was one of the consultants who attended the late King George VI, and for these services he was appointed C V O in 1951

A colleague writes

When George Mather Cordiner was appointed to St George's Hospital in 1935 he was already making a name for himself in the radiological study of gastro enterology, and before long he had a world-wide reputation in this field. His unassuming manner cloaked a high intelligence and an unflagging capacity for work Many of us were aware that he held decided opinions on the question whether the National Health Service was in the best interests of patients and of the medical profession, but this did not prevent him from carrying out with enthusiasm and devotion the work to which he had set his hand In this connection a great debt of gratitude was owed to him, especially by St George's Hospital To his unostentatious generosity I and many other of his younger colleagues, can bear witness

Dr Cordiner leaves a widow and a son and a daughter

ALBERT EDWARD MORTIMER WOOLF

M B Camb , F.R C.S

Mr Mortimer Woolf, consulting surgeon to Queen Mary's Hospital for the East End, a past president of the Hunterian Society and the present editor of its *Transactions*, died on April 6 at his home at Loughton, Essex

He was born in 1884, the son of the late Mortimer Woolf, O B E , and he was educated at Clifton College and Emmanuel College, Cambridge He completed his medical studies at the London Hospital and qualified in 1908 While holding house-appointments at the London he took his F.R C S in 1909 He was already finding his way in consultant practice when the war came, and he spent the next years serving as a surgical specialist with the R.A.M C in France, Mesopotamia, India, and Serbia After he returned to civilian life he joined the staffs of Queen Mary's Hospital for the East End, the British Red Cross Rheumatic Clinic, St. Margaret s Hospital Epping, the East End Maternity Hospital and the Lord Mayor Treloar s Home at Alton

Mr Woolf gave practical form to his admiration for John Hunter through his devoted service to the Hunterian Society For many years he was its honorary secretary and he was elected president from 1926 to 1928 and again in 1945 He was also for long the society s librarian and since the late war he had edited its *Transactions* His aptitude for this work was seen in his own papers many of which dealt with surgery of the gall-bladder and other aspects of abdominal surgery In one of his presidential addresses to the Hunterian Society in 1928 he examined pain from the surgeon's point of view, and in his Hunterian oration in 1931 he followed Hunter's example by turning to comparative anatomy for help in the elucidation of the problems of diverticulitis

D T D writes

There was something of Mr Pickwick in Mortimer Woolf Many of his friends called him Teddy and his presence in any company was always palpable as well as visible His joy in human company, his quick spontaneous laughter, his delight in jokes made him countless friends Like Mr Pickwick he was not unendowed with the goods of the world, and he was able to foster good causes and spend much of his time in making other people content

It mattered not whether it was exhorting the Hunterian Society to business, or whether it was discussing some topic at the dinner-table, or whether it was showing to friends the ancient trees in his delightful garden—it was done with great fun and with tremendous relish To Mortimer more than to anyone the Hunterian Society owes its present lively condition, and no council or committee or dinner of that society was ever complete without some quip or some words of wisdom from Mortimer Woolf Every institution that was fortunate to have him a member soon realised that every ounce of his enormous boundless energy would be used for that institution s welfare

He was a big man, big in physical frame and with a healthy florid complexion, his mind was also large tolerant, and honest and he was always ready to hear the troubles of those afflicted and to give all the help he could to ease them on their way

One sunny afternoon I watched him show with pride his garden to another great gardener, the late Lord Horder , and it was amusing to see the one examining the other in knowledge regarding the soil and regarding the health and the diseases of trees It was an examination conducted by one on the other, and I think that after some two hours both would have passed each other as being reasonably qualified in the knowledge they possessed of some of Nature's secrets

Mr Woolf married Miss Laura Nathan who survives him with their two daughters

THOMAS ARCHIBALD

M D Glasg

Dr Archibald who for 36 years, until his retirement in 1951, was physician-superintendent of Belvidere Hospital, Glasgow, died on March 26

A native of Greenock, he was educated at Allan Glen's School and Glasgow University, where he graduated in medicine in 1908 He joined the staff of Belvidere Hospital in 1911, and became its physician-superintendent in 1915, at a time when infectious disease was a much greater menace to life and health than it is today He found himself in charge of a busy hospital often full to overflowing, and often called to meet emergencies, such as the almost yearly outbreaks of typhus fever, or unusual incidents, such as outbreaks of cerebrospinal fever and encephalitis lethargica With the years he saw a decline in the incidence and a striking reduction in the severity of the commoner infectious diseases, and he played no small part in applying and assessing modern methods of treatment and prevention When he retired in 1951 tribute was paid to the administrative resourcefulness and clinical acumen which had enabled him to share so effectively in the work of reducing the death-rates and complications of infectious diseases " He did not seek the limelight, but went about his hospital work in a quietly efficient and admirable manner and could be regarded indeed as the ideal physician-superintendent, placing first the interests of his patients and his staff "

In his retirement Dr Archibald became a keen gardener and was justly proud of the results which he achieved by the same gifts of good husbandry and attention to detail that he had shown in former years in his professional work. He is survived by his widow.

GEORGE MITCHELL

M D Aberd., D.P H

Dr Mitchell, dermatologist to the Royal Hospital, Wolverhampton, from 1919 to 1945, died on April 6 at the age of 81 He graduated at the University of

Aberdeen in 1903, and took the D P H the following year, and the M D in 1905 After a short time in general practice he entered the public-health service, and from 1910 to 1912 he was chief school medical officer for Aberdeenshire He spent the next two years as assistant M O H and tuberculosis officer for Rochdale During the 1914–18 war he served with the R A M C After he was demobilised in 1919 he was appointed to take charge of the venereal-diseases services for Wolverhampton, which were centred in what is now the Royal Hospital, and he held this post until he retired in 1951 His interest in diseases of the skin grew steadily and in recognition of his work in this specialty a department of dermatology was set up and he became the first dermatologist to the hospital

J H S writes

George Mitchell was held in peculiar regard by all his colleagues in hospital, and by the practitioners of the district His personality evoked a mixture of the deepest affection and respect Respect for his intellectual abilities and intellectual honesty—two qualities by no means always synonymous—respect for his clinical judgment and integrity of life, qualities which to many of us seemed to typify the granite of his native country, but which by themselves could nevertheless suggest a personality essentially cold By contrast it was his warmth and sense of humour which seemed to enlarge and almost transfigure his mental equipment—so that in the course of time he became a central figure beloved by all.

Notes and News

IMPERIAL CANCER RESEARCH FUND

IT is hoped that demolition will begin this year in preparation for the new laboratories in Lincoln's Inn Fields[1] In view of the expansion of research expected when the new buildings are complete, the clinicopathological research committee has been replaced by a research advisory committee to advise the council on the scientific aspect of all its activities The new committee, whose chairman is Prof G F Marrian, F R S, is actively considering what research will be done in the new buildings Dr A M Begg and Mr H G Crabtree of the scientific staff have both retired this year

The report includes some account by Dr James Craigie, F R S, director of the central laboratories, and Prof Geoffrey Hadfield, director of the clinicopathological research unit, of work in progress This includes study of a possibly increasing malignancy of cells in a growth, of the behaviour of cancer cells in the presence of various gases, of the changes (if any) in a tumour which has been frozen, and of methods of determining œstrogens Material from the " frozen tumour bank " has been provided to other research establishments The survival is reported of malignant cells for as long as seven years, without evident loss of viability

COLLECTION OF PRESCRIPTION CHARGES

IN his annual survey[2] of the National Health Service accounts for England and Wales for 1955–56, the Comptroller and Auditor General expresses concern about the collection of prescription charges by dispensing doctors In August, 1953, the Ministry informed a number of executive councils that the returns of charges collected by dispensing doctors had varied greatly between one area and another and, in general, charges collected were a good deal less than might have been expected Only 24 of the 47 councils concerned seemed to be satisfied with the rate of collections

Returns for later periods, the Comptroller says, have shown little improvement In 1954–55 remittances for all areas averaged about 1 8 statutory charges for the year for each patient on the dispensing lists, whereas collections averaged about 3 per patient for the year for patients whose prescriptions were dispensed by chemists For doctors who were paid for prescriptions actually dispensed, the Comptroller's auditors reported many cases where remittances from doctors appeared inadequate in relation to the number of prescriptions dispensed and, occasionally, no remittances at all had been made during the year

The report concludes " Consideration had been given to the possibility of some abatement of the payments to dispensing doctors to take account of the charges they were required to collect But it had not been found possible to negotiate a fixed abatement which, bearing in mind the conditions of rural dispensing practices, would be fair to all capitation doctors This did not apply with the same force to the minority of doctors paid at drug tariff rates, but it had been agreed to accept the British Medical Association contention that they had similar difficulties in collecting charges, and that the adequacy of their collection of charges should therefore be assessed under the same procedure " The Exchequer and Audit Department proposed to remind executive councils of the need to investigate cases in which the amount surrendered appeared to be inadequate

MENTAL FACETS OF MATERNITY CARE

THE latest memorandum submitted to the Maternity Services Committee deals with psychiatric matters[3] It points out that the mental health of mothers is one of the most important factors governing the well being of our children, and that pregnancy and parturition are responsible for a significant proportion of mental ill health It recommends that the psychology of sex, pregnancy, and infancy, and the psychological abnormalities of pregnancy, labour, and the puerperium should be included in the training of obstetricians, midwives, and health visitors Knowledge of the special emotional factors in illegitimacy is important Education for parenthood should begin in childhood, this demands further study

---

[2] H M Stationery Office Pp 41 3s

[3] Memorandum for submission to the Maternity Services Committee Royal Medico Psychological Association, 11, Chandos Street, London, W 1

The memorandum calls, as did previous ones,[4] [5] for coordination of the services, antenatal care and labour should be conducted by the same team Antenatal education should be given to both parents The pregnant woman must be given a proper explanation of what is coming, and she should never be left alone during labour Analgesia must always be provided in case antenatal training has not abolished pain Soon after birth, home help must be provided—by relatives, or otherwise if the relatives are unsuitable Finally, there must be provision for psychiatric care of those mothers who, during pregnancy or the puerperium, show psychiatric symptoms The commoner psychological upsets associated with pregnancy are set out

SCOTTISH REGIONAL HOSPITAL BOARDS

THE following doctors have been appointed to the hospital boards New appointments are indicated with an asterisk

Northern region—*James Ronald *M M Whittet
North eastern region—R J Duthie, *Prof John Craig
Eastern region—*Prof George Bell
South eastern region—Prof G H Percival and G C G Mercer
Western region—W W Galbraith, *J C J Ives and *Major General J M Macfie

SPEECH CORRECTION

A PUBLIC symposium was held in London on April 8 to demonstrate results achieved in the correction of speech defects by Mr H V Hemery, L R A M Those who spoke were all at present members of Mr Hemery's class, which has been held at Goldsmiths' College, New Cross, S E 14, for the past twelve years All read their speeches but all delivered them clearly and audibly, apart from a few failures by less experienced students The courage and self confidence of the speakers was particularly striking and illustrated how Mr Hemery's skill and personality had convinced them that they could overcome their disability All the speakers told of definite improvement achieved through recognition of basically faulty speech methods and progressive re education in proper use of the vocal apparatus Diagnosis of speech errors and early training are conducted individually, but speaking before others from the earliest possible stage of treatment is an essential part of the re education course The course has no set length but most stammerers with an established pattern of stammer are said to require up to two years' re education

There will be an informal demonstration of impromptu speaking by members of the class on May 18 at 6 P M, at Goldsmiths' College, and the next public symposium will be held on June 27 at 6 30 P M

TWO VALUABLE PAMPHLETS

Two pamphlets by Dr Edward Glover—one on homosexuality[6] and the other on prostitution[7]—deserve wide circulation That on homosexuality includes humane and intelligent comments on the present state of affairs, and also a good deal of original fact from the records of the Portman Clinic and from the results of circulating a questionary The Home Office committee to which this evidence was presented must have found it a refreshing spring of factual information in a wilderness of undocumented opinion. Dr Glover has the courage to stress the foundations of the current public estimate of homosexuality in ignorance and psychopathology, and to point out the origins of the persecution directed at supposed "perverts" by people over reacting to homosexual components in their own make up He refuses to compromise by acquiescing in the demand for "treatment instead of punishment" in cases where there is neither disease nor crime His careful though brief account of the persons and practices involved, from about 100 case-records, does much to explode the idea that there is any sharp division between "homosexuals" on the one hand and non homosexual individuals on the other

Dr Glover s discussion of prostitution here in its 2nd edition, is equally humane, though slightly harder to read. His account of the defects of personality which lead women to become prostitutes will meet few objectors if it is applied wholly to our own society and period, but the institution has wide roots, and its form and personnel have varied widely—it seems doubtful whether Dr Glover's conclusions would have applied to the colleagues of Rahab, to ancient India, or even to modern France or China This cultural aspect is important, for we are perhaps, on the evidence of history, more likely to be able to transform prostitution than to abolish it

RECRUITMENT OF NURSES AND MIDWIVES

FROM May 1, some of the functions of the Ministry of Labour and National Service for the recruitment of nurses and midwives will be transferred to the Ministry of Health and the Department of Health for Scotland The National Advisory Council on the Recruitment of Nurses and Midwives, which has hitherto advised the Minister of Labour and National Service, will be reconstituted and will henceforth advise the Health Ministers The Health Ministries will be responsible for the general oversight of recruitment activities and for controlling the use of the mobile nursing exhibitions and the mental health exhibitions By agreement with the ministries, regional hospital boards will organise these exhibitions and talks to schools

The nursing appointments service of the Ministry of Labour and National Service will continue and will provide, through its 166 nursing appointments offices, a placing and advisory service for those who wish to train or work as nurses or midwives The service will also be available to medical auxiliaries Regional hospital boards, hospital management committees, local health authorities, the Services and other employing authorities will, as before, notify their nursing and midwifery vacancies to the nursing appointments offices The Ministry of Labour will retain the services of their principal nursing officer and a small number of technical nursing officers

CLEAN BLANKETS

Dr Blowers and his colleagues[1] have drawn attention to three new types of blanket which may be boiled, and we may hope that such blankets will be introduced in hospitals But this will take a long time, and meanwhile any economically possible means of making the existing blankets safer will be of interest

Mr Leslie Bird, chairman of the laundry subcommittee of the Newcastle Regional Hospital Board, has done some controlled experiments to test an ordinary commercial shrink-resisting process in pure woollen blankets[2] 12 blankets were treated and 12 not, 6 in each group were washed in commercial and 6 in hospital laundries They were used normally in the wards between washings The shrink resisting process itself led to an inconsiderable loss of size After 17 washings the untreated blankets had become too short, and after 19 too narrow, to be used The treated blankets were still extensive enough for use after 60 washings, but had lost weight They could still be used as extra blankets and (unlike the untreated blankets) retained their fleecy handle and whiteness

These findings do not hold for boiling, which inevitably damages woollen blankets, but a low temperature sterilisation process[3] did not damage the treated blankets Another interesting finding is that untreated blankets which have shrunk not too badly can be restored to usefulness by stretching while wet, followed by the shrink resisting process Mr Bird estimates that the minimum annual economy if these processes were adopted would be £35 19*s* per hundred beds

BRITISH STANDARD FOR HEAVY-DUTY HELMETS

A STANDARD for heavy duty industrial safety helmets has now been published A standard for light duty helmets, chiefly for coalminers, was prepared three years ago The new standard provides for helmets which will be sufficiently strong to protect the wearer's head from more severe blows They are intended for use by workers in structural engineering—notably on building sites, at oil refineries, in shipbuilding, and in mining and quarrying While the light duty standard prescribes a shock absorption test of 28 ft lb the heavy-duty standard prescribes a test of 40 ft lb Helmets to the new standard will be heavier and will cost more than the light-duty variety Employers should consult helmet makers as to which kind their employees need to wear Copies of this standard (4*s* each) may be obtained from the British Standards Institution, sales branch, 2, Park Street, London, W 1

University of Dublin

Dr Frank B Walsh, associate professor of ophthalmology in Johns Hopkins University, Baltimore, will deliver the Montgomery lecture on Friday, May 17, at 5 P M He is to speak on ocular movements associated with regeneration of the third nerve Prof Adolph H Schultz, director of the anthropological institute of the University of Zürich, will deliver the John Mallet Purser lecture on Tuesday, May 21, at 4 30 P M His subject is to be Past and Present Views of Man's Specialisations Both lectures will be given at Trinity College

National University of Ireland

Mr Seaghan O'Beirn has been appointed to the professorship of surgery at University College, Galway

Prof Edward Keenan has been coopted a member of the senate in place of the late Prof John McGrath

Royal College of Physicians of Ireland

On April 5, the following were admitted to the licence of medicine and midwifery of the college

A S A Atchia, Beryl D Chalkley, S P J Halpin R W Kneafsey, M B Labode, G K Maghrajh, S V McAndrew, A G McInerney, H J O'Brien, C P Quinn, A C Walsh

British Association

This year the association will meet in Dublin from Sept 4 to 11 under the presidency of Prof P M S Blackett, F R S

International Congress of Group Psychotherapy

This congress will be held in Zürich from Aug 29 to 31 Further particulars may be had from Dr Adolf Guggenbuhl Craig, Lenggstrasse 28, Zürich 8, Switzerland

Assurance Medical Society

A meeting of this society will be held at 5 P M on Wednesday, May 1, at 11, Chandos Street, London, W 1, when Dr A H Douthwaite will speak on some dangers of therapeusis

Death Grant

The time allowed for claiming a death grant under the National Insurance scheme has been extended from three months to six months

Central Midwives Board

Mr Arnold Walker has been re elected chairman of the board, and Prof A A Moncrieff deputy chairman, for the coming year

Chalmers Medal

The council of the Royal Society for Tropical Medicine and Hygiene have awarded this medal for 1957 to Dr A J Haddow, director of the Virus Research Institute, Entebbe, Uganda

National Society of Children's Nurseries

The annual general meeting of this society will be held on Thursday, May 30, at 4 P M at 45, Russell Square, London, W C 1 At 4 30 P M Prof W S Walton will give an address on Mothers at Work

Indian Medical Service Dinner Club

The annual dinner of this club will be held at the East India and Sports Club Ltd, St James's Square, London, S W 1, on Friday, June 7 at 7 30 P M Tickets may be had from the secretary of the club, Medical Board Room, Commonwealth Relations Office, Matthew Parker Street, S W 1

Collegium Internationale Allergicologicum

The following officers have been elected for 1957–58

President Dr David Harley vice president, Dr J Duchaine, Brussels, hon secretary, Dr P Kallós Helsingborg, treasurer and executive secretary, Dr A Cerletti, Basle

Other members of council include Dr R R A Coombs and Dr W S Feldberg, F R S

Prof A C Frazer has been appointed a member of the food panel of the World Health Organisation

A travelling scholarship fund has been founded by Sir Edward and Lady Baron to enable junior members of the staff of the corneo plastic unit and regional eye bank Queen Victoria Hospital East Grinstead, to visit foreign clinics, and to continue their studies of the joint problems of plastic and ophthalmic surgery

COURSE AND MANAGEMENT OF HIRSCHSPRUNG'S DISEASE

G G WYLLIE
M B Adelaide, F R C S
LATE RESIDENT ASSISTANT SURGEON, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

Hirschsprung described the disease which bears his name in 1888 For the next sixty years there was no significant advance in its treatment, though one of the basic pathological lesions was observed on a number of occasions Dalla Valle (1924), Cameron (1928), Robertson and Kernohan (1938), Whitehouse and Kernohan (1948), and Zuelzer and Wilson (1948) all noted an absence of parasympathetic ganglia in part of the bowel, but the significance of this finding was not generally recognised Confusion undoubtedly occurred because of the tendency to group together under the common name of " megacolon " all cases of enlarged colon

Since 1948 advances in the treatment and understanding of Hirschsprung's disease have been notable The disease has been recognised in the neonatal period, its pathology has been understood, accurate diagnosis has become possible, and a rational treatment has been evolved A striking reduction in mortality has followed these advances

Swenson and Bill (1948) found that the obstruction could be attributed to inability of the distal narrow bowel to produce coördinated peristalsis and that resection of the rectum and rectosigmoid region, with preservation of the anal sphincter, led to dramatic clinical improvement

Bodian et al (1949) then showed how cases of Hirschsprung's disease could be distinguished from other cases of enlarged colon on clinical, radiological, and pathological grounds They demonstrated further a uniform pathology in Hirschsprung's disease, accounting for the lack of parasympathetic function, and they thus offered a scientific basis for Swenson's operation

The genetic study by Bodian et al (1951), the physiological studies of Hiatt (1951), and the investigation of newborn infants by Ehrenpreis (1946, 1955) have all helped to further our understanding of this disease

Diagnosis and treatment, however, need careful consideration and may be difficult in some atypical cases Delay in diagnosis may be as serious as mismanagement, for the disease is a severe one and critical episodes are relatively frequent

I describe here experience with 152 cases of Hirschsprung's disease treated in the Hospital for Sick Children, Great Ormond Street since 1948, and draw particular attention to the problem of management in infancy Hirschsprung's disease is a relatively common cause of intestinal obstruction in the neonatal period and in infancy, and the diagnosis often can be made early in life Correct treatment at this stage greatly simplifies the subsequent management

Clinical Features

Neonatal Period

Details of the immediate postnatal period have been ascertained in 127 cases Some abnormality occurred during this period in 119 of the infants

The abnormal signs vary considerably There may simply be some delay in the passage of meconium or, at the other extreme, the full clinical picture of low intestinal obstruction may develop

The passage of meconium characteristically is delayed for two or three days, and then it is passed only after a finger or tube has been inserted into the rectum, or meconium may be passed regularly but in small amounts It then tends to flow more freely towards the end of the first week, though it is usual for the change of the character of the stool, caused by digested milk to be delayed

Vomiting is common Vomiting of bile stained fluid was recorded in a quarter of our cases, the true figure may be higher, for some vomiting during the neonatal period is so often accepted as normal There is often reluctance to feed even if there is no vomiting Commonly the baby is taken from the breast or the feed changed in the mistaken belief that the difficulty is primarily one of feeding management

Abdominal distension is common In about half the cases in this series it occurred during the first week—usually about the third day

Typically, therefore, the baby on the second or third day is not feeding well, perhaps is regurgitating a little has slight abdominal distension, and has passed little or no meconium On rectal examination at this stage the anus looks small but dilates normally to admit a fifth finger The rectum is empty and above it the narrower rectosigmoid region can be appreciated On withdrawal meconium and gas usually are passed

In some cases the signs are less severe

Operations during the first week were performed on 16 babies in this series, in this or another hospital, but probably efforts to deflate the bowel were inadequate in some Hirschsprung's disease itself was responsible for the obstruction in 14, while Hirschsprung's disease was associated with small-bowel volvulus in 1 and with internal hernia in 1 The bowel was found dilated above the aganglionic segment, and usually a cone was recognisable The segment involved the rectum and rectosigmoid region in half the cases and was unusually long in the remainder, extending into the small intestine in 2 Colostomy or ileostomy were performed in 6 cases, appendicectomy for associated appendicitis with perforation in 1, and deflation by a tube passed into the rectum in 7

Infancy and Childhood

Constipation is the outstanding symptom It is severe and generally unabated But some patients pass stools regularly for weeks or even months, especially during infancy The baby may then seem healthy to both parents and doctor, though some abdominal distension may be present and the motions tend to be small

Most commonly the stools are small and hard, even during infancy Straining during defæcation is also common in infants The times of onset of constipation in 138 cases in this series are shown in table I In a few cases, whilst the constipation could be dated from early in life, it did not become troublesome until early childhood One boy had no constipation until he was 4, but his abdomen was distended by that time Thus there are exceptions to the rule that constipation begins at birth and is obstinate

TABLE I—TIMES OF ONSET OF CONSTIPATION IN 138 CASES

Onset of constipation	No of cases
At birth	114
2 weeks–3 mos	13
4–6 mos	5
7–12 mos	4
Over 1 yr	2

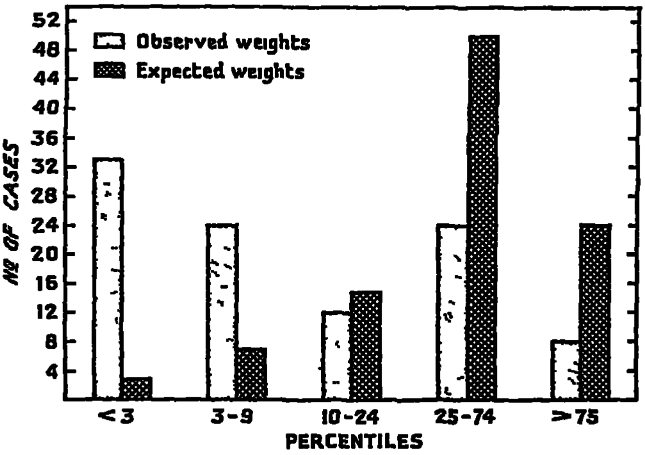
Episodes of more acute intestinal obstruction tend to occur, especially in infancy and early childhood Vomiting and abdominal distension result from retention of fæces and gas above the aganglionic segment Constipation is usual at these times, but " putrefactive " diarrhœa occurs in some cases and gastro enteritis may be superficially simulated These infants quickly become ill Toxic signs and dehydration are superimposed on malnutrition Abdominal distension may be extreme Findings on, and the response to, rectal examination are usually characteristic The rectum is empty, but the finger-tip may pass through the narrower rectosigmoid region into dilated colon On withdrawal, fluid fæces and gas are expelled under great pressure in a typically explosive way

Abdominal distension develops at or shortly after birth in the majority of cases Occasionally it is not noticed until the child is 2 or 3 years old Gas rather than fæcal masses is responsible, and loud borborygmi and visible peristalsis are common Quantities of foul smelling flatus are passed, particularly during the night, thus reducing the abdominal distension The distension is generally progressive, but it may vary from time to time It causes the characteristic flaring of the ribs and eversion and downward displacement of the umbilicus

Vomiting is not uncommon in infancy It is unusual after infancy except during obstructive crises

Growth is often retarded, especially in children with severe symptoms The weights of 109 children before treatment are shown in the accompanying figure Most were underweight, but 8% were above the average for their age Sexual development may be retarded, and puberty may be delayed in untreated children Hiatt (1951) and Kempton (1954) have described adults showing dwarfism and sexual infantilism

The findings on rectal examination in most cases are typical—i e, a narrow empty rectum with fæces at its upper limit or palpable in the sigmoid colon through the rectal wall But fæces filled the rectum at every examination in 4 of these cases, and in a further 22 there was usually some fæces extending down to just above the anal canal The initial diagnosis was wrong in 8 cases, chiefly because of the finding of a full rectum The abnormal segment was short and confined to the lower two-thirds of the rectum in most of these cases, but in some liquid fæces had probably trickled down to the rectum and solidified there A narrow empty rectum is of great value in diagnosis, but the absence of this sign does not exclude Hirschsprung's disease



Weight percentiles of 109 untreated cases of Hirschsprung's disease

Severity of Symptoms

The variation in the severity of symptoms between different cases is quite striking One child may not be seriously disturbed for some years, whereas another will have acute obstruction and be severely ill in the first days of life Yet the two have apparently identical lesions The length of the aganglionic segment is an important, though clearly not the only, factor In the present series several of the newborn infants with obstruction had affected segments of average length, whereas a boy with aganglionic bowel extending into the ileum did not come to hospital until he was $3^1/_2$ years old and was not operated on until he was 5 But usually the cases with long affected segments present early in life

TABLE II—CAUSES OF NEONATAL INTESTINAL OBSTRUCTIONS AMONG ADMISSIONS, 1949–53

Causes	No of cases
Jejuno ileal atresia	33
Duodenal atresia	18
Malrotation	15
Meconium ileus	14
Hirschsprung's disease	15

Hirschsprung's disease, unlike other forms of chronic obstruction associated with enlargement of the colon, carries a high mortality without treatment Formerly, many infants died of obstructive crises and few survived to adult life

Diagnosis

In most cases the diagnosis can be strongly presumed on clinical evidence Confirmation is first sought by radiology, the opaque enema is a most useful diagnostic aid in patients of any age, and it has established the diagnosis in babies a few days old Interpretation of the findings in young babies may be difficult, however, for at this age the contrast between the unexpanded segment and the colon above it may be slight and the examination may therefore have to be repeated

Rectal biopsy (Swenson et al 1955) has proved a most useful diagnostic measure In the present series specimens were obtained by submucous resection and the diagnosis was based on the state of the submucous parasympathetic plexus (Bodian 1956) Our experience has been similar to Swenson's, and the technique has been of most value in the following instances (1) with unusually long aganglionic segments, (2) with unusually short segments (part of the rectum), (3) where a colostomy has been established without confirming the diagnosis and the bowel below it has assumed a uniform calibre, (4) where doubts are raised by unusual symptoms or radiological appearances

Differential Diagnosis

During the Neonatal Period

Anal stenosis—The anus in Hirschsprung's disease often looks very small, as it does whenever gas and meconium have not passed through it It dilates without any sense of constriction on the passage of a fifth finger into the rectum, though the skin at the anal verge may split slightly and a little blood is seen after withdrawal This is a normal finding and does not represent anal stenosis The rectum normally narrows at the recto sigmoid junction and only the tip of the finger can be passed through it This finding is mistaken sometimes for a stenosis, but both stenosis and atresia at the site are extremely rare

Other types of intestinal obstruction—The clinical picture of Hirschsprung's disease may resemble very closely that of other forms of neonatal intestinal obstruction It is important to distinguish between them, however, for Hirschsprung's disease is often better treated conservatively at this stage whereas the other conditions mostly need urgent operation The incidence among admissions of newborn infants with intestinal obstruction during a five year period (1949–1953) is shown in table II

The signs of obstruction in atresia are usually established by the end of the first day, whereas a similar appearance in Hirschsprung's disease may not be seen until the second, third, or fourth day The findings on rectal examination tend to be similar—an undilated anus, an empty rectum, and narrower rectosigmoid region It is the response which is different In Hirschsprung's disease withdrawal of the finger is followed usually by the passage of enough meconium and gas to reduce the degree of distension In the presence of atresia some meconium may be passed, but it is drier than usual, a plug of white mucus may precede it, and it has no effect on the distension

Plain radiography is the most useful investigation If dilated large bowel can be identified, Hirschsprung's disease should be considered seriously, for it is much the most likely cause of colonic obstruction at this age But it may not always be recognisable, for the haustrations become taken up in the general distension of the colon above the aganglionic segment The type of Hirschsprung's disease with a long aganglionic segment extending into the ileum generally presents as a small-bowel obstruction and cannot be distinguished from the other forms

It may not be possible, then, to diagnose Hirschsprung's disease in the neonatal period until laparotomy is performed If, at operation, distension is found to extend into the large bowel and is succeeded by a cone-shaped narrowing, the diagnosis will be clear Where Hirschsprung's disease causes a small-bowel obstruction, dilatation and hypertrophy give way gradually to a narrow distal ileum The appearance may resemble that seen in meconium ileus In Hirschsprung's disease, however, the hypertrophy is less, and the meconium is above, rather than in, the narrow segment and is less viscous

During Infancy

Feeding problems—These may be suggested by vomiting and failure to thrive, but the history and physical signs should enable a distinction to be made

Constipation—This is usually much more severe and intractable in Hirschsprung's disease than constipation due to other causes in infants Hard fæcal masses may be felt in the colon above the narrow segment, this is uncommon in other forms of constipation in infants

Gastro enteritis—The acute episodes which tend to occur during infancy may simulate gastro enteritis Vomiting, abdominal distension, and frequent motions are seen in both states, but the stools are green in gastro-enteritis and usually yellow in Hirschsprung's disease The response to rectal examination may be similar except for the colour of the fluid ejected

Cœliac disease—This may be simulated by a failure to thrive and abdominal enlargement, but the history and the nature of the stools usually enable Hirschsprung's disease to be diagnosed clinically

During Childhood

Colonic inertia (idiopathic megacolon)—The diagnosis during childhood must be made primarily from colonic inertia (Bodian et al 1949) The history may be most useful, for it dates from shortly after birth in so many cases of Hirschsprung's disease whilst this is much less common in the other forms of constipation In colonic inertia, abdominal distension is slight or absent, fæcal masses, as opposed to accumulations of gas, are present, there are less borborygmi and flatus, and often there is overflow soiling, the rectum is always filled with fæces

Management

Incorrect early treatment may make subsequent management unnecessarily difficult It has been our aim to develop a standard programme for each circumstance until Swenson's operation can be performed

In the neonatal period if the signs are mild a finger or tube passed into the rectum will usually establish the flow of meconium This procedure should be repeated as necessary if meconium, and later stools and gas, tend to be retained At first many infants do not need any treatment other than this, which enables them to feed satisfactorily and to gain weight

If the signs are more severe, the abdomen should be X-rayed Hirschsprung's disease can be suspected if the small bowel gas shadows are uniform and large-bowel dilatation extends to the left side of the abdomen If rectal examination fails to produce a significant amount of meconium and gas colonic lavage should be carried out This must be done with great care, for the wall of the bowel may be thin and perforation is possible, either by the tube or from increased tension within the lumen Accordingly the surgeon himself should carry out this manœuvre, which, if it deflates the colon, will have averted the need for operation

If the diagnosis is not made until laparotomy, treatment will depend on the length of the aganglionic segment If the cone is at the rectosigmoid junction or in the lower part of the sigmoid colon, a rectal tube should be passed by an assistant and guided by the operator into the dilated bowel Deflation can be achieved in this way, and a colostomy avoided as subsequent bowel washouts can be expected to keep the colon empty

An enterostomy is necessary if the abnormal segment extends further along the bowel It should be sited just above the cone if this is in the descending colon or the left half of the transverse colon Full use is thus made of the normal colon, for the colostomy is brought down to the anus at the definitive operation When the aganglionic segment extends beyond the middle of the transverse colon, choosing the site may be difficult There have been instances of an apparent cone in the right half of the colon where the abnormal segment has in fact, extended into the ileum A colostomy then does not relieve the obstruction In these circumstances the small bowel should be examined carefully for hypertrophy and inequality in size Coning in the small intestine is much more gradual than in the rectosigmoid region and some gas, though very little meconium, may extend well down into the aganglionic ileum and even into the colon Frozen sections during operation are of great assistance in determining the correct site for enterostomy An ileostomy is the safest procedure if there is doubt and frozen sections cannot be examined, especially if part of the small bowel is hypertrophied

Meconium ileus must be considered when there is a hold-up of meconium in the small bowel and an unexpanded colon Usually the distinction is clear, for the abnormal meconium impacted in the lower ileum has a characteristic appearance and feel But there are occasions when it is more mobile and the dilatation and hypertrophy of the ileum above are less pronounced The appearance in long segment Hirschsprung's disease may be very similar Again, it is wise to perform an ileostomy if there is doubt

There are two essential points about an ileostomy in any of the above circumstances It should be sited carefully, and it should be accompanied by biopsy of the bowel wall It is easy to make the enterostomy in aganglionic bowel, for the coning is gradual, and ganglion cells may not be present except in the most dilated and hypertrophied intestine Apparent hypertrophy alone is a less reliable guide to normal innervation than it is in the colon Biopsies are also necessary to establish the diagnosis It is a simple matter to take a biopsy specimen from the ileostomy wall This will confirm that the ileostomy is in ganglionic intestine or provide a warning if it is not A biopsy specimen of the rectal mucosa should be taken at the end of the operation if the baby's condition is good enough This is preferable to sectioning the wall of the unexpanded colon at the time of the laparotomy

The majority of affected infants do not need operation in the immediate postnatal period If necessary their gut can be deflated by a tube or finger passed into the rectum as has been described Their progress should then be watched closely Gaseous abdominal distension may be controlled by the passage of a flatus tube or finger regularly before feeds Many babies feed well and thrive on this régime, but constipation may quickly become obstinate

If the baby becomes constipated, the diagnosis should be confirmed at once by barium enema Such confirmation depends on contrast between the bowel above and that below the transitional area, and this is seen best when the infant is constipated, the contrast may be lost after bowel washouts If the result is negative or doubtful, the examination should be repeated under similar circumstances after three or four weeks

After the diagnosis has been established, bowel washouts should be given regularly if constipation is at all troublesome They are not necessary in all cases, but a close watch must be kept on infants who are not having treatment, for an acute obstructive crisis may quickly develop and need treatment urgently Daily bowel washouts have proved satisfactory, saline is used and all fluid run in is recovered, the danger of water intoxication is thus greatly reduced In Hirschsprung's disease an ordinary enema is dangerous

Acute obstructive episodes usually can be overcome by bowel washouts, but an emergency colostomy is needed occasionally The aim of early recognition of Hirschsprung's disease is to avert severe constipation, recurrent crises, and the need for an emergency colostomy Instead, malnutrition can be avoided and the infant helped to thrive so well that Swenson's operation can be performed at an early age This is often possible from the age of about 6 weeks onwards

After ileostomy more strenuous efforts are needed to ensure a reasonable weight gain, and if the condition remains unsatisfactory colectomy and ileo anal anastomosis may be undertaken earlier than planned There is less urgency after a correctly placed colostomy, which is usually followed by weight gain and progress, though there is a tendency to hypochromic anæmia

Occasionally Hirschsprung's disease causes mild symptoms and the case may not present until later infancy or early childhood Some patients go through childhood with no more inconvenience than that of a slightly enlarged abdomen and moderate constipation which responds to aperients, but even these children may suffer from physical and sexual retardation, and their condition would be improved by Swenson's operation, which I regard as the treatment of choice in practically all cases

Summary

The signs of Hirschsprung's disease begin at birth in the majority of cases, and most cases can be recognised early in infancy

Before definitive surgical treatment by resection of the aganglionic bowel, management should be designed to prevent obstructive episodes and consequent retardation of growth

Ordinarily enterostomy is best avoided

I acknowledge most gratefully the cooperation of the consultant staff of the Hospital for Sick Children in allowing me to study their cases, and of the research committee which made possible the investigations I am particularly indebted to Mr Denis Browne, Dr Martin Bodian, and Mr H H Nixon for much personal help and for allowing me to draw on their great experience My thanks are also due to Mr Derek Martin and Mr G Lyth, of the department of medical illustration

TREATMENT OF HIRSCHSPRUNG'S DISEASE BY SWENSON'S OPERATION

G G WYLLIE
M B Adelaide, F R C S
LATE RESIDENT ASSISTANT SURGEON, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

IN 1948 Swenson and Bill showed that in "congenital megacolon" there was functional obstruction in the region of the rectum and rectosigmoid, and that resection of this normal looking bowel beyond the dilated colon, with preservation of the anal sphincter, was the rational treatment Shortly afterwards, Bodian et al (1949) demonstrated uniform changes in Hirschsprung's disease —absence of parasympathetic ganglion cells from the intramural plexuses, and presence of abnormal nerve fibrils in the undilated distal segment This was considered a congenital lesion Experience has confirmed the value of these contributions

Many series showing most satisfactory results from this operation have been published (Bodian et al 1951, Hiatt 1951, Ehrenpreis 1952, Swenson and Sugarman 1954), but none of these reports includes a detailed description of bowel function after operation, though they report a satisfactory degree of continence It is commonly accepted that some rectal mucosa is needed to provide an adequate sensory stimulus for defæcation Goligher and Hughes (1951) stated that in their experience of adults it was necessary to retain 5–7 cm to ensure continence The resection is carried lower than this limit in the Swenson procedure, however, and it seemed desirable to go more fully into the late results of operation The present report describes experience of 152 cases of Hirschsprung's disease treated in the hospital for Sick Children, Great Ormond Street, by excision of the aganglionic segment

The term "rectosigmoidectomy" has tended to focus attention on the rectosigmoid region rather than on the rectum itself, and it is inadequate in describing resection of an abnormal segment extending beyond the sigmoid colon I suggest, therefore, that the procedure be known as "Swenson's operation," consisting of complete excision of the aganglionic intestine This principle was used in the operations in this series, though in the majority the technique was altered, as suggested by Denis Browne (1949), to perform resection after intussusception of the mobilised bowel through the anus

Clinical Material

The series comprises 128 boys and 24 girls who have undergone operation for Hirschsprung's disease since 1948 The longest period of follow up is thus 8 years

The early cases were mostly in older children who had survived the disease for some years, but it was quickly found that younger children and infants withstood the operation well and much malnutrition and chronic ill health was thereby avoided Diagnosis has been made increasingly often early in life during the past few years, and early operation has become the rule The youngest age at operation was 5 weeks The ages at which the definitive operations were undertaken are shown in the accompanying table

AGES AT OPERATION

Age	No of cases
5 weeks–6 mos	15
6–12 mos	18
1–2 yr	11
2–5 yr	36
5–10 yr	28
Over 10 yr	11

6 children had other congenital anomalies Cleft palate, hypertrophic pyloric stenosis, congenital disloca

tion of the hip, bilateral ectopic testes, cataract, and mental retardation each occurred in 1 instance

Preliminary Colostomy

Initially transverse colostomy was performed routinely, making three stages—colostomy, excision of aganglionic bowel, and closure of colostomy Since 1952 single stage operations have been performed increasingly commonly, and this has become the standard practice The following circumstances are now regarded as indications for preliminary colostomy

1 Acute obstructive episodes in the neonatal period or infancy which cannot be relieved by bowel washouts Such babies may quickly become very ill

2 An unusually long narrow segment, revealed at laparotomy, causing an obstruction which cannot be relieved by guiding a rectal tube into the dilated bowel Such segments usually extend beyond the sigmoid colon, even into the ileum, and in this event ileostomy is necessary

3 Infants who do not thrive despite regular bowel washouts

4 Older children with advanced disease and gross colonic dilatation and hypertrophy Defunctioning colostomy then leads to improvement in general health and reduction in size of the dilated bowel, thereby reducing disproportion and facilitating the subsequent anastomosis

Site

In almost all cases submitted to preliminary colostomy, the site of this was the transverse colon This site has the advantage of leaving the lower abdomen free for the definitive operation Transverse colostomy is well withstood by infants, but hypochromic anæmia tends to develop, and, though they may look well, their hæmoglobin level should be checked regularly during the interval between operations Difficulty has been experienced in some cases with aganglionic segments extending to the proximal sigmoid colon and beyond There may then be insufficient normal colon beyond the colostomy to reach the bottom of the pelvis, and it may be necessary to perform left hemicolectomy and to bring down some part of the right colon This adds to the complexity and danger of the operation

An alternative site for the colostomy, used only twice in this series, is in the left hemicolon at the level of the transition between aganglionic and normal bowel (Swenson 1955) This level is determined, if necessary, by biopsy Subsequently the colostomy is resected along with the aganglionic bowel, and continuity is restored at the definitive operation, thereby reducing the number of operations from three to two Thus full use is made of the length of normal colon, and the procedure has the added advantage that at the subsequent operation the bowel to be brought down is predetermined However, it has the disadvantage of bringing the colostomy into the operation, and there may be difficulty in choosing the correct site in the neonatal period in cases with long segments, the apparent cone may then be in aganglionic bowel The surest way of correctly siteing the enterostomy in such cases is by rapid frozen sections

Technique

In Hirschsprung's disease the dilated sigmoid loop may extend well into the upper abdomen, and often it is the first segment of colon to present through an upper abdominal incision It has been mistaken for the transverse colon

The site of the cone should be marked with a black silk stitch which can be identified at the subsequent operation In some very ill young babies it may not always be expedient to perform the formal laparotomy which this manœuvre needs, but rather a small upper abdominal incision through which a loop of transverse colon can be brought out It is important then to attempt to identify the site of the cone by radiography as soon as the baby is fitter for the bowel beyond a colostomy may quickly assume a uniform calibre

Operation

Preparation

The essential measure is to empty the large bowel The general health usually improves remarkably as this is done

Daily colonic lavage has proved the most satisfactory method of emptying the colon In some long-standing cases many weeks of treatment may be necessary, but nutrition, which is poor in such cases, improves steadily during this period and the time is well spent In Hirschsprung's disease, enemas are generally ineffective and are potentially dangerous They should not be given

Fitness is so essential that if, as occasionally happens, these measures do not lead to a satisfactory gain in weight and improved nutrition, a colostomy should be established

Anæmia may require correction, especially in children who have colostomies Immediately before operation the bowel is prepared by an oral bacteriostatic or antibiotic agent Both succinylsulphathiazole for 5 days and streptomycin or oxytetracycline for 2 days have been used in this series and have proved effective

Technique

The Swenson technique (Swenson and Bill 1948), as modified by Dennis Browne (1949, 1955), has been used in the majority of the cases Single-stage operations were performed on 66 children, whilst 86 had preliminary colostomies

A simple small table maintaining the child in the semi-lithotomy position with a sheet barrier between the exposed abdominal and perineal fields has been found most useful (fig 1) Two surgical teams are needed, and, the patient being small, care in organisation around the table is important

An intravenous infusion is established so that blood may be given slowly from the start of the operation A urethral catheter is inserted and left draining It is a wise precaution to have a stomach tube in situ, for the small bowel has to be packed off for a considerable period and the colostomy closed temporarily

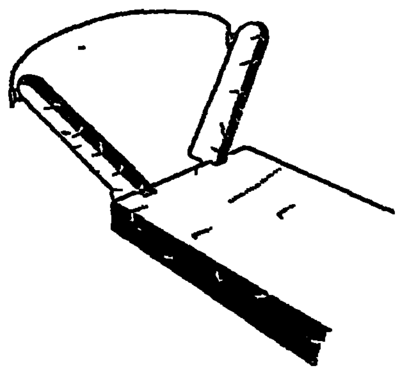

Fig 1—Operation table

On opening the peritoneal cavity, the large bowel may be distended with gas A useful measure then is to guide a sigmoidoscope, passed by an assistant, into the dilated colon

The operation consists in mobilisation of the aganglionic bowel right down to the anal canal, the dissection below the peritoneal floor being made on the rectal wall This dissection is time consuming, for there is no ready plane of cleavage, but it is facilitated by the use of divulsers (Browne 1955) These instruments enable the tissues to be split into strands suitable for ligation or diathermy coagulation

In selecting the site of proximal section, the most important factor is that it should be in normally ganglionic bowel Hypertrophy has been found a satisfactory guide in this regard, but recently, in cases of doubt, frozen sections during operation have been used They have been found particularly helpful in cases with long aganglionic segments where a colostomy has been established without a marking suture at the cone In experienced hands this method has proved wholly reliable

When the proximal bowel is widely dilated the upper section should be as high above the cone as is allowed by the vascular arrangement in the sigmoid mesentery and the length of available colon If very dilated bowel is anastomosed to the anus a terminal reservoir is created, and the risk of postoperative constipation increased It is important to mobilise sufficient colon to avoid any tension on the suture line low in the pelvis Mobilisation of the splenic flexure helps in this respect, and is particularly valuable in cases with rather long sigmoid segments

The rectal dissection has to be continued down to the anal canal Unless this is done the canal cannot be intussuscepted fully and the lower section will be made leaving behind a segment of rectum The distal transection should be made immediately above the anal canal and the anastomosis carried out 1–2 cm from the anocutaneous junction Even with such a low resection children achieve continence This low section is made in all cases, because Hirschsprung's disease may result from very short lengths of aganglionic intestine and because symptoms may recur if abnormal bowel remains below the anastomosis The anastomosis, made in the perineum after intussuscepting the mobilised bowel, is facilitated by preliminary dilatation of the anus, retraction of the buttocks, and the use of a suture plug (Browne 1955) If exposure is poor, or the dissection inadequate, the anastomosis tends to be too high

Recently at the finish of the operation a drainage tube has been placed in the pelvis in the space around the anastomosis and continuous suction applied in the postoperative period It is believed that this measure will reduce the incidence of pelvic infections

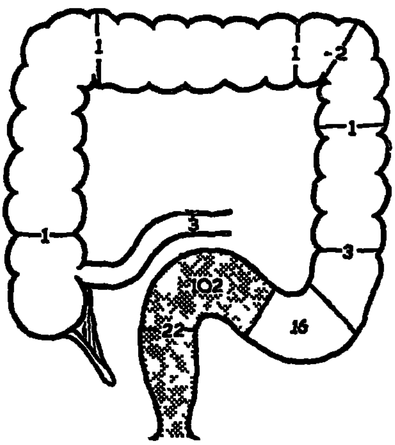

Fig 2—Proximal extents of aganglionic segments in 152 cases of Hirschsprung's disease

The aganglionic segment involves the rectum and lower sigmoid in the majority of cases In the remainder the segment may be shorter or longer The lengths in our series are shown in fig 2

The surgical approach in the long-segment cases may have to be modified to give access to the splenic flexure and even the whole colon

In cases with short segments, the bowel may be hypertrophied and dilated down to the pelvic floor and the cone not seen until dissection is carried out below the peritoneal reflection

Postoperative Management

Children withstand the operation well and usually are in good condition at its end as long as there has been adequate blood replacement The intravenous infusion generally is stopped after 24 hours, when fluid by mouth can be given Catheter drainage of the bladder is continued for 24 hours, but, should the catheter become dislodged before this time, replacement is seldom needed Chemotherapy is desirable, and we have given penicillin 10,000 units per lb body-weight 8-hourly and streptomycin 20 mg per lb per day for 5 days Some children, especially younger ones, develop gaseous colonic distension during the first few days after operation This should be relieved by a flatus tube passed carefully beyond the anastomosis—a measure which may be necessary every few hours Indwelling rectal tubes have been used in an attempt to prevent this distension and two small tubes, side by side so as to allow gas to escape between them, have proved satisfactory

The bowel acts usually after 48–72 hours Motions at first are loose and frequent, but become more normal in consistency and reduced in number by the time the child is ready to leave hospital The time taken for the bowel movements to become normal depends largely on the age of the child and the length of colon remaining

In general the uncomplicated postoperative course is quiet and free from restlessness Experience has shown that restlessness is often the first sign of some complication

Complications

The operative and postoperative periods were satisfactory in 117 of the 152 cases In 35 some complication, either early or late, occurred, and of these children 9 died 6 deaths were at, or shortly after, operation, while 3 occurred later This gives an operative mortality of 4% and an overall mortality for the series of 6%

Shock

Shock was responsible for 3 deaths 2 were early in the series when blood replacement tended to be inadequate and the 3rd was of a young infant who received insufficient blood in error Great importance is now attached to early and adequate blood replacement during operation

Ischæmic Necrosis of the Distal Colon

This caused 2 deaths In both, previous surgical procedures complicated the operations

The 1st case, a boy who had survived from the pre 1948 series, had had eight previous operations, including partial colectomy, and after resection of the aganglionic segment the colon passed under some tension directly from the transverse colostomy to the pelvis

In the 2nd case, a colostomy had been established in the middle of the transverse colon, but at the definitive operation the aganglionic segment was found to extend to the lower descending colon As there was insufficient colon beyond the colostomy to reach the anus the middle of the transverse colon was brought down on the right branch of the middle colic artery after mobilising the hepatic flexure

Extreme restlessness and shock characterised the postoperative period in both cases Death occurred after 36 hours and 55 hours respectively In each case at necropsy the colon was found under tension, and in the 2nd case the middle colic artery was in spasm

These cases illustrate the disadvantage of a colostomy in the transverse colon when the aganglionic segment is longer than usual Greater length of colon would be available by siteing the colostomy immediately above the cone, as has been described already Further experience has shown that the ascending colon, with the ileocolic artery, can be turned down into the pelvis without tension This procedure is now our standard practice when there is insufficient normal colon beyond a transverse colostomy

The ischæmic bowel is deeply situated in the pelvis and cannot be seen at laparotomy Proctoscopy may be useful if this complication is suspected

Pelvic Infection

This complicated 9 operations 1 child died after the development of peritonitis and septicæmia Infection has followed both single and staged procedures 6 followed one stage and 3 multiple stage operations This incidence is not high for this type of operation, and it should be reduced further by improvements in technique made during the series

The consequences of the infection were peritonitis in 6 cases, discharge of pus into the bowel through the suture line and subsequent stricture formation in 2, and ischiorectal abscess with fistula in 1

For peritonitis the procedure used was to remove all free fluid and establish a transverse colostomy

With the exception of the fatal case mentioned this led to remarkable recoveries

A single-layer anastomosis has been used in the great majority of the operations A small experience of a two-layer technique has shown that this does not eradicate the possibility of pelvic infection. It is believed that the pelvic drainage tube with suction, now being used, will lessen it

Infection is known to precede stricture formation in some cases, and whenever pus is discharged per rectum regular digital examinations of the suture line should be made

Disruption of the Wound

This occurred in 6 cases, following single-stage operations in 4 The ruptures occurred about the fifth postoperative day All the patients made uneventful recoveries

Intestinal Obstruction

This developed in 7 cases 2 children died and 5 recovered. In 4 cases the obstruction occurred early in the postoperative period and in 3 later The early cases were small-bowel obstructions due to peritoneal adhesions in 1 these dated from the colostomy operation. All recovered after laparotomy. The 3 later obstructions were each caused by a small-bowel volvulus—a month 6 weeks, and 8 months after operation Operation was delayed in 2 cases and both patients died

It should here be emphasised again that the normal postoperative course is smooth and that persistent restlessness should suggest the possibility of a strangulating or obstructive lesion Abdominal distension and vomiting early after operation might also result from a hold-up of gas in the colon above the anastomosis, but in this event the passage of a flatus tube will give relief The later obstructive episodes have to be distinguished from faecal impaction, which may lead to a somewhat similar clinical picture, but the child with faecal impaction does not become ill nearly so quickly, and the findings on rectal examination and the dramatic response to colonic washout are characteristic It has to be remembered, too, that the child with a small-bowel volvulus may continue to pass frequent loose stools

Anastomotic Stricture

This developed in 7 cases In some others the suture line felt tight temporarily but responded quickly to digital dilatation and healed without stenosis The majority of strictures were in young infants, and several had rather long segments with the likelihood of some tension on the anastomosis. Infection also was a significant factor in at least 2 cases

These cases emphasise the importance of full mobilisation of the left hemicolon whenever transection has to be in the upper sigmoid region and some tension would otherwise occur

The strictures generally developed within the first 3 weeks, but on two occasions were delayed for three months There is a need therefore for regular rectal examinations both early and later during the postoperative follow-up

Treatment by regular digital or instrumental dilatations is necessary. This may have to be continued for many months and even years in some cases 1 of the cases was cured only after dilatations had been continued for 3 years

The result in 4 cases has been correction of the stenosis and the development of normal bowel function while a further 2 are progressing favourably under this treatment 1 boy in whom an impassable stricture developed presumably after disruption of the anastomosis continues to have a colostomy; a further attempt to restore continuity is contemplated

Urinary Retention

Urinary retention, leading to chronic distension with overflow, occurred in 1 of the very early cases in the series Temporary cystostomy was followed by a return of detrusor function The boy now has full urinary control Since this case the rectum has been dissected against the muscle coat itself and there have been no similar urinary complications

Functional Colonic Distension

The 9th death was that of an infant aged 14 months 5 months after operation. He was admitted to another hospital in a collapsed state following an enema, given because of vomiting and abdominal distension He died within a few hours and at necropsy no organic obstruction was found Possibly his death was due to water intoxication

Functional Results of Operation

Children still less than 3 years old who could not be expected to be fully continent, and children operated on during the past 3 months have been excluded from this assessment. This leaves 102, whose ages range now from 3 to 22 years A recent survey shows that 55 are normal in every way The remainder still have some deficiency but in the majority this is slight and in many the result was regarded as imperfect only because it was desired to make a most critical survey of the operation.

The three most important aspects are general health, bowel regularity, and continence

General Health

This has been outstandingly improved by the operation Parents uniformly report improvement in appetite vigour, and general fitness For the first time in many cases schooling has been free from repeated interruptions Some of those early in the series are now carrying out National Service, and 1 has finished this Those at school can take a full part in games

The weights and heights were studied in a series of 40 cases (fig 3) In the majority these were at or above the average for the age and in some a considerable deficit had been made good

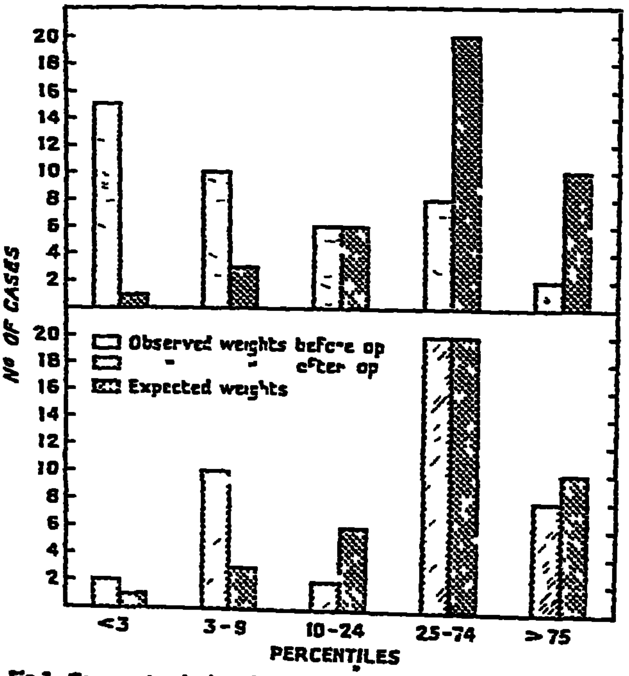

Fig 3—Comparative body-weights in 40 cases before and after operation

Bowel Regularity

There is considerable individual variation in the development of regular defæcation after operation. In most children this develops easily and at once, while others are prone to constipation and normal function is attained slowly.

Constipation is one of the most common problems in management. It required treatment in 34 cases in this series, of whom two-thirds were less than 3 years old at the time of operation. In most the trouble began within a few months of operation, but in 9 cases it was delayed for more than a year—even for as long as 3 years. 7 of them presented because of incontinence or frank soiling, and 10 with vomiting and abdominal distension.

The acute episodes with vomiting and distension were similar to the crises seen in the untreated disease. They occurred mostly in the under-2-year group, and there was a decided tendency to recurrence. Large quantities of soft fæces and gas under pressure were retained in the colon, though in some there was frequent overflow soiling. Vomiting soon became progressive, and several of these children were ill and dehydrated when admitted. The importance of the matter is emphasised by the death already mentioned. There was a dramatic response to rectal examination or intubation—fluid stool and gas were ejected with a great force—and the child's condition improved immediately, though active resuscitation might be necessary.

In other children fæcal accumulations, without much gas or distension, developed slowly. Often stools continued to be passed during this time; it might be recognised that these were smaller or less frequent than usual, or the parents might notice nothing abnormal until overflow incontinence occurred. Examination showed the rectum right down to the anus filled with fæces, which usually were soft.

The management of the two groups was essentially the same—the colon was emptied and kept empty until regular defæcation returned. It was often most satisfactory to readmit the child to hospital to begin the treatment. Later regular aperients and bowel washouts once or twice a week could be continued at home. Treatment was continued until complete evacuations occurred regularly. More than two years' treatment was necessary in 14 of our cases, but experience justified this conservative approach. Of the 34 cases in which constipation occurred, 24 are now passing motions regularly, while the remainder are still under treatment. As constipation was corrected, control improved.

There are probably two important factors in the production of this *postoperative constipation*. One is sensation, for until the sensation caused by a motion in the new "rectum" is appreciated by the child he may ignore it, and as a result fail to empty the terminal bowel; the higher incidence of constipation in young children is probably significant in this regard. The child must be sent regularly to the lavatory in the early stages, and it may be desirable to use aperients to ensure adequate evacuation.

The second important factor is the size of the colon proximal to the point of resection. Often the colon is considerably dilated and liable to empty incompletely, and treatment may be needed then to prevent the development of the "colonic inertia" syndrome.

The level of the distal section may be a further factor in the development of postoperative constipation. It is important to remove all the rectum and anastomose the colon directly to the proximal end of the anal canal.

Careful follow-up, including regular rectal examinations, is necessary as large fæcal accumulation may develop quite insidiously after a normal period as long as 3 years.

The long period of treatment needed in a few cases before regularity and control are gained has to be borne in mind when a revision operation for removal of a supposed small residual abnormal segment, is under consideration. Revision operations have been performed in 3 cases. In 1 case the gut resected at this further operation was ganglionic except for a small transitional area; while in another a further 2·5 cm. of aganglionic bowel was excised from below the suture line: good function resulted. Such limited resections have been accidental, but the fact that conservative treatment of many cases of postoperative constipation has ultimately led to a good functional result should be borne in mind when further surgery is being considered.

Continence

Of the 102 children now more than 3 years old, 61 have achieved full continence. In 41 there is lack of full control, but in most this lack is slight. Most of the children are still of an age when, in this respect, many normal children are not wholly reliable at times of excitement or loose motions, but in the follow-up survey continence was assessed in the strictest possible light. The individual variation in the time taken to gain full control after operation is considerable, but the reason for this is not always clear.

Most of the group with normal function became continent within a few weeks after operation, but a few children soiled for several years before acquiring perfect control.

Control is good in nearly two-thirds of the remaining 41 cases. The defect is now no more than occasional slight soiling of the perianal region, though in some cases this state has been reached only after a period of more heavy soiling. The tone of the anal canal is normal in practically every case.

The commonest time for soiling is before defæcation. Much less common times are after defæcation, at night, and when passing flatus. Urgency, especially early after operation, causes a few children to soil.

Attention to continence is one of the most important aspects of management after operation. In many cases constipation is an important cause of incontinence, and improvement in control usually follows correction of constipation.

Bowel training after operation is another important factor. Up to the time of operation many of these children have never experienced the normal sensations associated with defæcation and have not within memory had a bowel action without some aid. Afterwards they have to learn the sensations—and perhaps unusual ones at that—from the beginning. It is hardly surprising that some children are slow to achieve complete control. That soiling is commonest before defæcation suggests that they fail to realise, or realise too late, the need for defæcation. Bowel training after operation is therefore very important. Inevitably the social circumstances, the age and intelligence of the child, and the interest of the mother bear on the problem. Children should be trained to defæcate at regular times and aperients given as necessary. If they are left to their own devices there is a danger of sensations being ignored and of constipation developing insidiously.

A very satisfactory degree of control has been achieved by children who have had ileo-anal anastomosis because the whole colon was aganglionic. Soiling has been slight, and in the oldest case has almost stopped. About 3 stools are passed each day after the first 6 months.

Enuresis

15 children over the age of 4 years have nocturnal enuresis; all have perfect control by day. In 7 it is the only disability, for they have normal bowel function. Several parents have noted that bed-wetting is more frequent when the rectum is full.

This is a higher prevalence of enuresis than would be expected in normal children, but is probably not significantly higher than in those who have undergone any other embarrassing and uncomfortable illness and a major operation in childhood

Pyelograms have not been performed routinely, but during an earlier follow-up intravenous pyelography was carried out in 25 cases, none showed any significant abnormality Also, the ureters are always seen at operation, and no abnormal dilatations, such as those described by Swenson et al (1952), have been seen in this series

Summary

Swenson's operation has been undertaken in 152 cases of Hirschsprung's disease at the Hospital for Sick Children, Great Ormond Street

The operative mortality was 4% and the overall mortality 6%

The complications are described and their treatment discussed

Bowel training and prevention of constipation are necessary after operation

I acknowledge most gratefully the coöperation of the consultant staff of the Hospital for Sick Children in allowing me to study their cases and the research committee who made possible the investigation I am particularly indebted to Mr Denis Browne, Dr Martin Bodian, and Mr H H Nixon for much personal help and for allowing me to draw on their great experience My thanks are also due to Mr Derek Martin and Mr G Lyth, of the department of medical illustration

XANTHOMATOSIS AND ESSENTIAL HYPERCHOLESTEROLÆMIA

HOUSE PHYSICIAN, HAMMERSMITH HOSPITAL, LONDON

THE earliest descriptions of tendinous and tuberous xanthomas appear to be those of Addison and Gull (1857) and Fox (1879) Fagge (1873) observed the association of xanthomatosis and cardiovascular disease, and Müller (1938) noted the high incidence of angina of effort among his patients with xanthomatosis

Burns (1920) demonstrated the defective cholesterol metabolism present in this syndrome

The familial nature of the condition was mentioned by Torok (1893) and Gossage (1908), and many genetic studies of the syndrome have been made in America and Norway during the past twenty years, but no such studies have been published in this country We therefore report here the clinical and genetic investigation of five families with xanthomatosis and essential hypercholesterolæmia

Material and Methods

Members of these families were, except for a few in the first pedigree, seen by one of us, and wherever possible an electrocardiogram was obtained

Serum cholesterol was estimated by a modified Bloor method following extraction by the method described by Clarke and Marney (1945) or, as in the second pedigree, by the method of Zlatkis et al (1953) In some cases oxalated plasma was used, which tends to give a slightly lower reading

For the upper normal level of serum cholesterol we have used the figures published by Keys et al (1950), who investigated the range of serum cholesterol in healthy people and its variation with age The upper limit for 98% of their population in each age-group has been accepted Previous investigators have used various figures for the upper normal limit for serum cholesterol and, with one notable exception (Piper and Orrild 1956), have disregarded its variation with age

The accompanying pedigrees have been compiled to illustrate both the clinical features of xanthomatosis and the transmission of hypercholesterolæmia Because of the large numbers involved we have not included cholesterol values in pedigree no 1 except for the small branch derived from I 3 Unless the individual is deceased, the symbols □ ○ therefore imply, in almost all cases, that the individual is considered to be normal on clinical grounds and to have a normal blood cholesterol level

Clinical Features

The clinical features of these patients were typical of those described by Thannhauser (1950) The corneal arcus was observed frequently among those with xanthomatosis but may be the only clinical expression of hypercholesterolæmia and therefore merits investigation, particularly in younger age-groups

Tendon xanthomas were found over the tendo Achillis, the extensor tendons of hands and toes, and the extensor aspects of the knee and elbow Xanthelasma palpebrum usually accompanied these xanthomas but was occasionally found alone or in conjunction with the corneal arcus

Of the 10 patients with hypercholesterolæmic xanthomatosis 8 had had ischæmic heart disease, which had been the cause of death in 4

Hypercholesterolæmia was observed in 38 persons, of whom 15 had ischæmic heart disease

Pedigree no 1 (fig 1)

Attention was attracted to this family by the patient, II 18, a member of the branch derived from I 3 She was one of four siblings with hypercholesterolæmic xanthomatosis and ischæmic heart disease, which proved fatal in two (II 19, II 21) The father (I 3) was known to have had xanthomatosis and died at the age of 53, the sole representative of the third generation (III 35) has angina of effort and hypercholesterolæmia

No further example of the complete syndrome, hypercholesterolæmic xanthomatosis, was found in this family, but many members with the incomplete syndrome (xanthelasma palpebrum, corneal arcus, ischæmic heart disease, and hypercholesterolæmia) were discovered, particularly in the first branch, derived from I 1 The frequency of coronary disease, often proving fatal at an early age, is of particular interest and is illustrated by a girl (III 24) who died at the age of 27 and was found at necropsy to have extensive coronary atheroma

Pedigree no 2 (fig 2)

The first patient (III 6) had had xanthomatosis and angina of effort since the age of 16 and electrocardiographic evidence of coronary occlusion at the age of 21 Her sister (III 7), who presented an identical picture, died of ischæmic heart disease at the age of 21 In both there was clinical evidence of involvement of the aortic valve

This sibship (III 6–III 9) was derived from a consanguineous mating of two members of a family in which there was further evidence of the incomplete syndrome (xanthelasma palpebrum, corneal arcus, coronary disease, and hypercholesterolæmia)

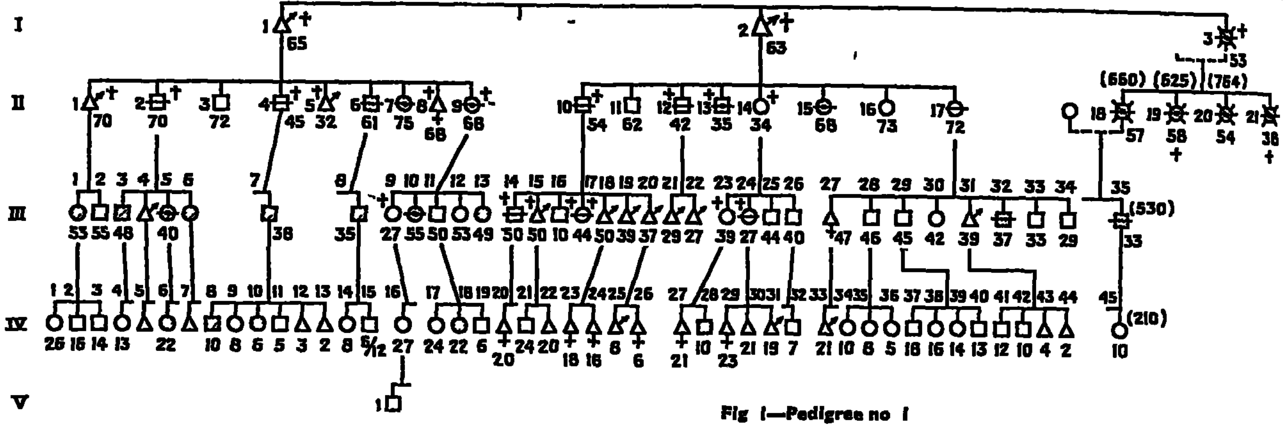

Fig 1—Pedigree no 1

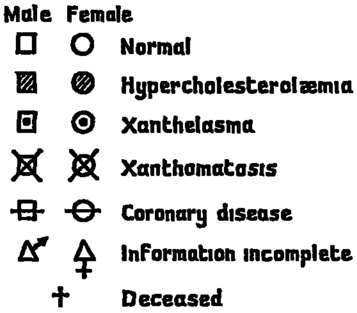

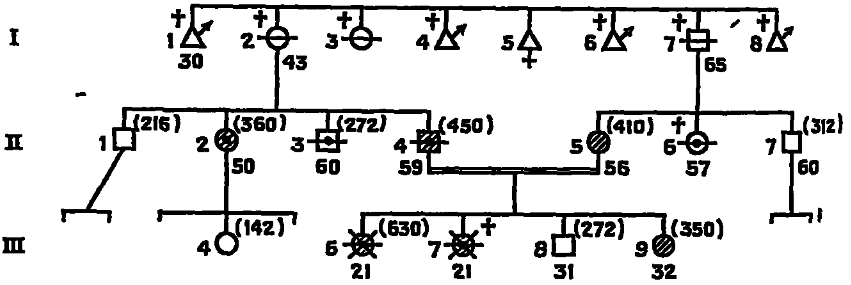

Fig. 2—Pedigree no 2 Symbols as in fig 1

Pedigree no 3 (fig 3)

The patient, II 2, was admitted after a coronary occlusion and found to have xanthomatosis There were examples of the incomplete syndrome in this small family, and her surviving siblings were shown to have hypercholesterolæmia

Pedigree no 4 (fig 4)

Clinical evidence of the syndrome in this family was confined to the patient, II 1, who had a well-developed corneal arcus and xanthomatosis, and his sister, II 3, who had a corneal arcus only, but familial essential hypercholesterolæmia was found later

Pedigree no 5 (fig 5)

Apart from the patient, II 3, who had xanthomatosis, there was no clinical evidence of the syndrome in this family, but hypercholesterolæmia was found in the siblings

Biochemistry

The basic abnormality in this syndrome is disordered metabolism of cholesterol, with xanthomatous infiltration of skin, tendon sheaths, and arterial intima as a secondary effect The relationship of some of these clinical features to the serum cholesterol level is shown in fig 6

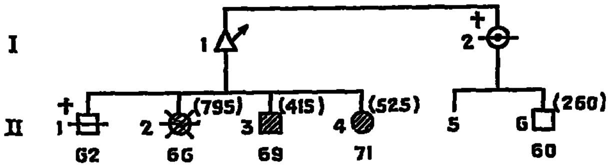

Fig 3—Pedigree no 3 Symbols as in fig 1

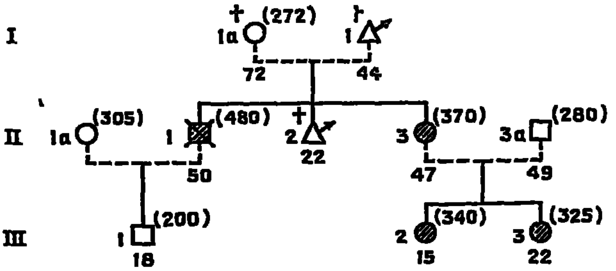

Fig 4—Pedigree no 4 Symbols as in fig 1

The concentration of fatty acids and phospholipids in the serum was estimated in a high proportion of the members of these families and usually found to be either high normal or slightly above normal The occurrence of a raised serum-uric-acid level in a significant proportion of individuals with hypercholesterolæmia, as reported by Adlersberg (1949), was confirmed

Paper electrophoresis was done on almost all the sera obtained from members of these families The increased density of the β-lipoprotein band characteristic of hypercholesterolæmic states was often seen

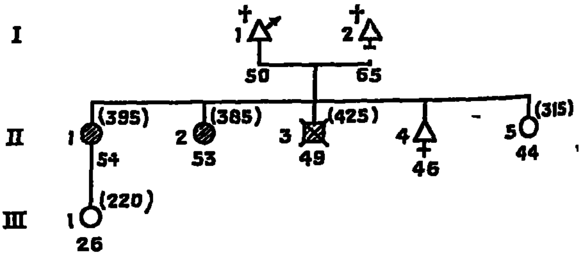

Fig 5—Pedigree no 5 Symbols as in fig 1

Genetics of Hypercholesterolæmia

This investigation was undertaken primarily to study the genetic pattern of essential hypercholesterolæmia At the start of this work the prevailing view was that essential hypercholesterolæmia was transmitted as an incomplete dominant trait (Wilkinson et al 1948, Adlersberg et al 1949, Alvord 1949, and Thannhauser 1950) Wilkinson et al (1948) considered that essential hypercholesterolæmia represented the heterozygous abnormal (Cc) and hypercholesterolæmic xanthomatosis the homozygous abnormal state (CC) for cholesterol On completion of the investigation of pedigrees 1–3 we considered that our results were compatible with this theory (Harris Jones et al 1956)

In tracing the genetic pattern in these pedigrees pedigree 1 (fig 1) is most conveniently considered in three sections

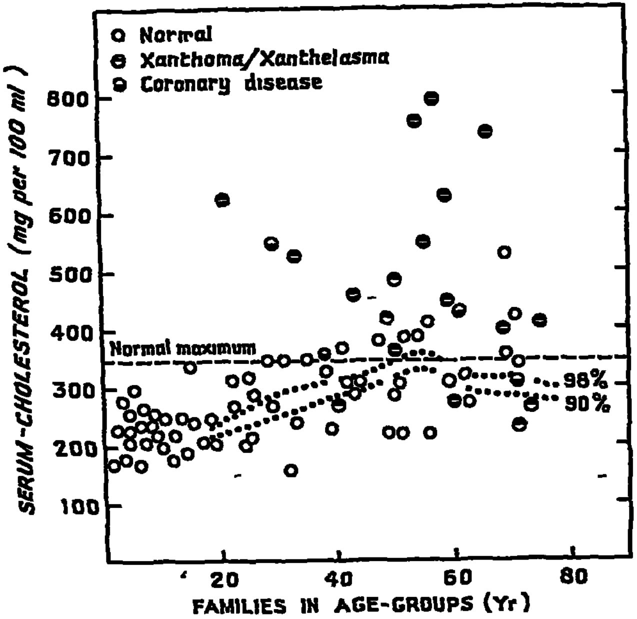

Fig 6—Incidence of xanthomatosis xanthelasma, and coronary disease and their relation to serum-cholesterol levels in pedigrees I–5 Dotted lines denote normal maxima of serum cholesterol levels in 98% and 90% of a population studied by Keys et al (1950)

In the first branch, derived from I 1, the transmission of hypercholesterolæmia follows a dominant pattern except for the kindred III 11 and IV 18, who require further investigation

In the second branch, derived from I 2, there was little clinical evidence of the syndrome, hypercholesterolæmia being found in only three persons Among the descendants of II 14, however, there is evidence of early death with coronary disease, xanthelasma, and hypercholesterolæmia (IV 28)

In the third branch, derived from I 3 there is a remarkable increase in both the frequency and severity of the condition. Here, according to the theory of Wilkinson et al (1948), we have a sibship of three, probably four, homozygotes (II 18–21) The undoubtedly rare mating of a homozygote (I 3) with a heterozygote has to be invoked to explain this The increased intensity of the syndrome in this branch might support this possibility The mating of a homozygote abnormal (II 18) with a normal person produced, as predicted, a heterozygote (III 35)

Pedigree no 2 appeared to provide evidence essential to the theory of homozygosis, according to which both parents of a person with hypercholesterolæmic xanthomatosis (CC) must be at least heterozygous abnormal (Cc) the sibship III 6–9, consisting of two homozygotes, one heterozygote, and one normal, was derived from the consanguineous marriage of two affected members (II. 4 and II 5) of a family with essential hypercholesterolæmia

Pedigree no 4, however, showed that the theory of homozygous heredity (Wilkinson et al 1948) was no longer tenable In this family (fig 4) both a parent I 1a) and a son (III 1) of the patient with hypercholesterolæmic xanthomatosis (II 1) had normal serum-cholesterol levels

Pedigree no 5 did not present an opportunity to clarify this point neither parents nor offspring of the patient with xanthomatosis (II 3) being available for study

The results of the investigation of these five families support the view expressed by Piper and Orrild (1956). who reviewed twelve families and confirmed that hypercholesterolæmia was transmitted as a dominant trait, but rejected the theory that xanthomatosis represented the homozygous abnormal state for cholesterol

Comment

The full syndrome of hypercholesterolæmic xanthomatosis is probably uncommon but its recognition should not be difficult The incomplete syndrome, which occurs much more commonly, appears to escape recognition more often

Essential hypercholesterolæmia should be considered when coronary disease, xanthelasma palpebrum, and corneal arcus are encountered, alone or in combination, in patients aged less than 50 The corneal arcus in particular appears to have received surprisingly little attention as a valuable clinical sign of hypercholesterolæmia The high incidence of coronary disease associated with essential hypercholesterolæmia and its alarming incidence in patients with xanthomatosis have been confirmed

Summary

Five families with familial xanthomatosis and essential hypercholesterolæmia are reported

Whereas essential hypercholesterolæmia is transmitted as a dominant trait, there is no evidence that xanthomatosis represents the homozygous abnormal state for cholesterol.

Essential hypercholesterolæmia and xanthomatosis is associated commonly with coronary disease of early onset

We are indebted to Dr C E Davies, Dr James Brown, and Dr J Carson for permission to study patients under their care, Dr A. Jordan, Dr T L Morris, and Dr F Young for their invaluable assistance, the many pathologists and practitioners who have helped us, and the Royal Society of Medicine for permission to reproduce fig 6 from their *Proceedings*

HYPERURICÆMIA AND ESSENTIAL HYPERCHOLESTEROLÆMIA

J N HARRIS JONES
M D Lond, M R C.P
SENIOR MEDICAL REGISTRAR, ROYAL HOSPITAL, SHEFFIELD

TOPHACEOUS gout is presumed to result from an inborn error of metabolism and is associated with a raised level of uric acid in the serum Essential hyperuricæmia may be detected in apparently healthy relations of a patient with gout

Xanthomatosis similarly results from an inborn error of metabolism and is accompanied by a rise in the serum cholesterol level Again a raised serum cholesterol level may be found in healthy near relations of patients with xanthomatosis

An interesting relationship between these two metabolic abnormalities was recorded by Adlersberg (1949) During an investigation of families of patients with xanthomatosis (Harris Jones et al 1956), the opportunity was taken to study this association

Methods and Material

The material for this investigation consisted of patients with xanthomatosis and their families In 85 people the serum

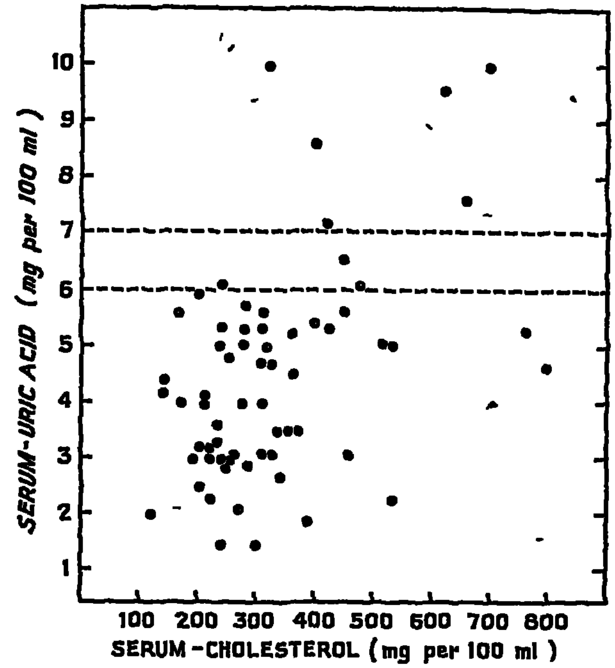

Fig 1—Relation of serum uric-acid levels to serum-cholesterol levels in patients with xanthomatosis and in their families

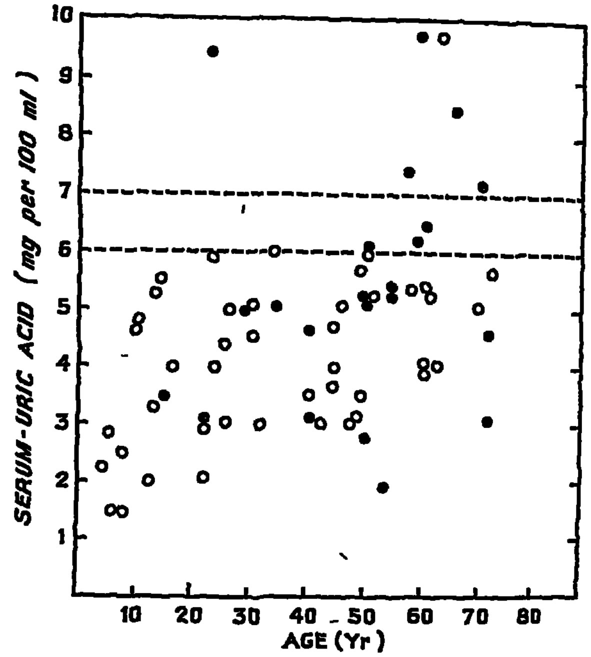

Fig 2—Serum uric-acid levels in relation to age and to hypercholesterolæmia in patients with xanthomatosis and in their families *open circles*, serum-cholesterol level normal, *solid circles*, hypercholesterolæmia

cholesterol level was estimated, and in 65 of these the level of uric acid in the serum was also estimated There were 32 women and 33 men in this group and the age range is shown in fig 2 7 members of this group had xanthomatosis, and there was a high incidence of ischæmic heart disease in their families (Harris-Jones et al 1957) No clinical evidence of gout was detected in these families The serum-cholesterol level was estimated by a modified Bloor technique after extraction by the method described by Clarke and Marney (1945), and in a few cases by the method of Zlatkis et al (1953) Oxalated plasma, known to give slightly lower results, was used on some occasions Because of the known tendency for the serum cholesterol level to rise with increasing age, its upper normal limit was based on the figures published by Keys et al (1950) The upper limit for 98% of their healthy population in each age group was taken, this ranged from 240 mg per 100 ml at 18 years to 364 mg per 100 ml at 55 years

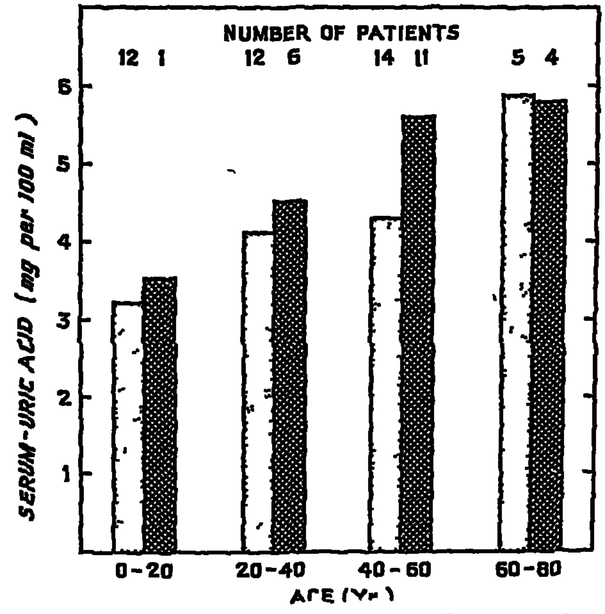

Fig 3—Mean serum-uric-acid levels in age groups of patients with and without hypercholesterolæmia *stippled*, serum cholesterol level normal, *hatched*, hypercholesterolæmia.

The serum uric acid level was estimated by the methods described by Kern and Stransky (1937) and Caraway (1955) The upper normal limit for serum uric acid was taken as 6 mg per 100 ml (Smyth et al 1948, Marson 1953) In a survey of serum uric acid levels in health and in coronary artery disease Gertler et al (1951) found that in only 6% of their controls and matched controls was the serum uric acid level above 6 mg per 100 ml, and that none were above 7 mg per 100 ml

RELATION OF SERUM-URIC ACID LEVEL TO SERUM CHOLESTEROL LEVEL

Serum cholesterol level (mg per 100 ml)	No of persons	Serum uric acid level (mean) (mg per 100 ml)
< 350	44	4
350 or more	21	5 5
< 400	49	3 9
400 or more	16	6

Results

Serum cholesterol and serum-uric acid levels of patients with xanthomatosis and their families are recorded in fig 1 Of these 65 people studied 22 were considered to have essential hypercholesterolæmia, 9 had a serum uric acid level above 6 mg per 100 ml, 6 of these having more than 7 mg per 100 ml All but 2 of those with a serum uric acid level above 6 mg per 100 ml and all but 1 of those with a serum-uric-acid level above 7 mg per 100 ml had a serum cholesterol level of 400 mg per 100 ml or higher

The relation of the serum uric acid level to age and hypercholesterolæmia is illustrated in fig 2, which shows the tendency for the serum-uric acid level to rise with age in both those with a normal serum cholesterol level and those with hypercholesterolæmia Of the 22 people deemed to have hypercholesterolæmia 8 had a serum uric acid level above 6 mg per 100 ml, 5 of these having more than 7 mg per 100 ml (Adlersberg [1949] reported that in a third of 37 patients with essential hypercholesterolæmia the serum-uric-acid level was 6 mg per 100 ml or higher) Of the 45 people with a normal serum-cholesterol level 3 had a serum uric acid level of 6 mg per 100 ml or higher, 1 of these having more than 7 mg per 100 ml, this finding is in keeping with values for healthy controls published by Gertler et al (1951)

The mean serum-uric-acid levels in those with hypercholesterolæmia and those with normal serum cholesterol levels in each age group is shown in fig 3 The mean serum-uric-acid level in relation to increasing serum-cholesterol level is shown in the accompanying table The striking rise in the mean serum-uric-acid level with the rising serum-cholesterol level recorded in the accompanying table is modified when this is studied in age-groups (fig 3) because the greatest number of people with essential hypercholesterolæmia will be found in the age group 40–60, a period in which the serum-uric-acid level usually reaches its highest values

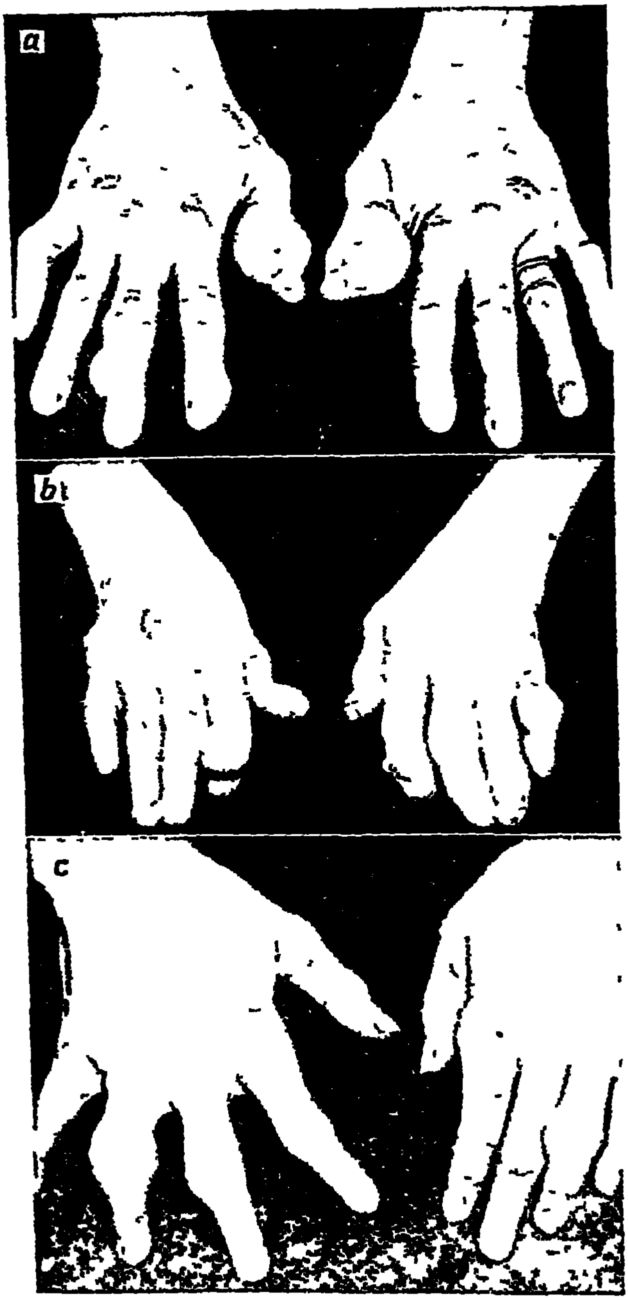

Fig 4—Hands of three women showing clinical similarities between gout and xanthomatosis tophaceous deposits on extensor tendons being indistinguishable from tumours of xanthomatosis *a* aged 58 with xanthomatosis serum-uric-acid level 9 7 mg per 100 ml., serum-cholesterol level 520 mg per 100 ml *b* aged 65 with gout, serum-uric-acid level 9 7 mg per 100 ml., serum-cholesterol level 260 mg per 100 ml *c* aged 22 with xanthomatosis serum-uric acid level 9 4 mg per 100 ml serum-cholesterol level 725 mg per 100 ml

Discussion

Essential or primary abnormalities of uric-acid and cholesterol metabolism are comparable in some of their genetic and clinical aspects Both result from an inborn error of metabolism which manifests itself clinically in only a small proportion of affected people It has been stated that hyperuricæmia, or the metabolic abnormality from which it arises, may be transmitted as a dominant autosomal gene (Smyth et al 1948), but Hauge and Harvald (1955) failed to confirm this It now appears established that the metabolic abnormality responsible for hypercholesterolæmia is transmitted as a dominant trait In some genetic studies it has appeared that the full clinical syndrome of both tophaceous gout and xanthomatosis multiplex represent the homozygous abnormal state for uric-acid and cholesterol metabolism respectively (Smyth et al. 1948, Wilkinson et al 1948)

Although tophaceous gout and xanthomatosis should easily be distinguishable clinically they have some features in common Both biurates and cholesterol esters tend to be deposited in sites of physical stress or trauma, such as the extensor aspects of joints, and in tendon sheaths This similarity of distribution of tophi and xanthomata is shown in fig 4 Estimation of the serum-uric-acid level alone might not differentiate these two conditions, but the serum-cholesterol level is almost invariably raised in xanthomatosis

Coronary-artery disease is reported to occur in about 40% of patients with essential hypercholesterolæmia (Piper and Orrild 1956) Clinical impressions of an association between gout and coronary-artery disease were supported by Gertler et al (1951), who found a positive correlation between hyperuricæmia and coronary-artery disease In attempting to relate ischæmic heart-disease to a biochemical index, these workers devised the "cup index," which is the product of

$$\frac{\text{serum cholesterol (mg per 100 ml)} \times \text{serum uric acid (mg per 100 ml)}}{\text{serum lipid phosphorus (mg per 100 ml)}}$$

Finally, although the metabolic abnormality in the form of hyperuricæmia or hypercholesterolæmia may be detected among the younger relations of patients with gout or with xanthomatosis, the emergence of the full clinical syndrome is uncommon in either before middle life

Although it is beyond the scope of this investigation to seek an explanation for this apparent association between hyperuricæmia and hypercholesterolæmia, some possible factors might be examined with interest. The possibility that tophaceous gout and xanthomatosis were both present in some patients was excluded by examination of the case-histories and the patients The chance inheritance of two inborn errors of metabolism for purines and for cholesterol, was rendered unlikely by the fact that three of the five families studied contributed members with hyperuricæmia

✓ The results of this investigation tend to direct attention to the effect of hypercholesterolæmia upon uric acid metabolism There is some evidence that high-fat diets inhibit uric acid excretion in man (Adlersberg and Ellenberg 1939), hyperlipæmia and hypercholesterolæmia have been reported in patients with gout (Albrieux et al 1953)

Before valid conclusions are possible, further and more detailed studies are desirable Such studies, which would include observations on the excretion of uric acid and the effect of cholesterol-lowering agents on the serum-uric acid level were impracticable because members of these families were so widely scattered Multiple blood sampling is also important in studying such variables as serum-uric-acid and serum cholesterol levels, and it is because this has been impossible that the results obtained have not been submitted to statistical analysis This report has aimed at attracting attention to the occurrence of hyperuricæmia among relations of patients with xanthomatosis, and to some of the genetic and clinical similarities between gout and xanthomatosis

Summary

Serum-uric-acid levels in patients with xanthomatosis and members of their families are reported

Abnormally high values were found among those with essential hypercholesterolæmia, the highest values being recorded in patients with xanthomatosis

There are clinical and genetic similarities between gout and xanthomatosis

There does not appear to be an obvious explanation for the association of these metabolic abnormalities

I am indebted to Dr A Jordan for biochemical estimations, and the Editor of the *Proceedings of the Royal Society of Medicine* for permission to publish fig 2

CLINICAL COMPARISON OF DIAMORPHINE AND PHOLCODINE AS COUGH SUPPRESSANTS

BY A NEW METHOD OF SEQUENTIAL ANALYSIS

E S Snell*
M B Lond, M R C P
SENIOR MEDICAL REGISTRAR, PADDINGTON GENERAL HOSPITAL, LONDON

P Armitage
M A Camb, Ph D Lond
MEMBER OF MEDICAL RESEARCH COUNCIL'S STATISTICAL RESEARCH UNIT, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

In view of recent controversy over the value of heroin in the relief of symptoms it seemed desirable to test one action of the drug in man by a controlled clinical trial

Heroin has gained the reputation of being the most powerful drug in the suppression of cough and, since this action seemed to be more susceptible to measurement than the relief of pain, the trial was designed to study this effect The trial compared the effect on cough of three preparations—linctuses of diamorphine (heroin), pholcodine, and a placebo The original intention was to use the ranking method described by Rushbrooke et al (1956) Difficulties arose with the method, and it was decided instead to compare the treatments in pairs by a new method of sequential analysis, the theory of which has been described by Armitage (1957)

Materials and Methods

The patients all had cough of several months' duration 2 patients were uncooperative and had to be excluded from the trial, and there remained 45 patients No attempt was made to assess the degree of cough, but its severity in all cases was such as to lead the patients to ask for relief and, in some, to keep them awake for several hours during the night There were 14 outpatients who all had chronic bronchitis, and 31 inpatients with the following conditions chronic bronchitis 17, pulmonary new growth 6, bronchiectasis 3, mitral stenosis 3, and chronic pulmonary tuberculosis 2 Most of the inpatients with chronic bronchitis were convalescing from additional illness—e g, acute respiratory infection, spontaneous pneumothorax, and congestive cardiac failure—but by the time of study their cough had recovered to its usual state

The linctus of diamorphine was prepared according to the *British Pharmaceutical Codex 1954* and contained diamorphine gr $^1/_{30}$ in each 60 minims, with oxymel glycerin, and syrup The placebo was an identical mixture except that diamorphine was omitted The pholcodine linctus ('Lipect,' John Wyeth) contained in each dose

Antazoline hydrochloride	12 50 mg
Pholcodine	4 00 mg
Ext ipecac liq	0 03 ml
Sucrose	3 20 g

Each mixture was taken, for two days, in a dose of minims 120 at night before the patient went to sleep, the whole course lasting six days The use of linctus at night rather than during the day would probably make it easier for the patients to assess the severity of their cough An expectorant linctus was given to some in the day, but apart from this no drugs were given which might have suppressed cough

In advance the hospital dispensary had arranged for the patients to receive the three drugs in such a way that the six possible orders were distributed randomly among each succeeding group of six patients The patients were numbered consecutively, and the mixtures were prepared in three bottles labelled with the patient's number and a number showing the order of administration—i e, 1st, 2nd, and 3rd No other means of identification appeared on the bottles, and the patients nurses, and observer were unaware of their contents When the mixtures were required the patient's number was shown on the prescription sheet and the appropriate series of bottles was delivered by the dispensary

The patients were told that they were receiving three types of medicine and that we wished to find out which relieved their cough best They were asked to note the severity of their cough from the time of taking the medicine until going to sleep, so that later they would be able to rank the three treatments in order of preference After the six day trial period their preferences were recorded, as bottle numbers, and, after each batch of six patients had been treated, the bottle numbers were interpreted as names of the corresponding linctus mixtures by reference to the dispensary list

Early in the trial it became clear that the patients were rarely able to give a clear set of preferences, because they usually gave a tie for first or last place, or even for all three mixtures (table i) For this reason the statistical treatment for ranking methods used by Rushbrooke et al (1956) would have had to be modified We decided at this stage to compare the treatments in pairs, using for any one pair of treatments only those patients who gave a clear preference in favour of one or the other We decided, in addition, to use a new type of sequential analysis, called a "restricted sequential procedure," the theory of which has been described by Armitage (1957) Since this method has not been used previously in clinical trials, its main features are described here

---

Sequential Analysis of Results

In sequential methods of statistical analysis observations are examined continuously as they become available, and the decision whether to stop at any stage or to make further observations depends on the results so far obtained Various sequential methods for use in clinical trials have been described by Armitage (1954) These methods had the useful feature that, for comparisons of two treatments, a trial could be ended relatively quickly if the treatments differed very considerably in efficacy, or if their effects were very similar. They had, however, the disadvantage that in intermediate situations the trial could last a very long time because there was no definite upper limit to the number of observations

Bross (1952) has given two sequential plans for medical trials, in which the number of observations is restricted to be less than some definite upper limit, and one of his plans has been used in a clinical trial by Newton and Tanner (1956) The "restricted sequential procedures" of Armitage (1957) are similar to those of Bross but provide a wider variety of plans suitable for different circumstances

The results are plotted on a chart (see figure)

Each of the three comparisons between pairs of treatments gives rise to a zigzag path starting at the origin (the point where the horizontal and vertical axes intersect) For each patient giving a preference in favour of one of the two treatments the path is continued one step in a "north-easterly" direction, for each patient giving the opposite preference the path moves one unit in a "south easterly" direction The area in which the paths develop is enclosed by three boundaries, shown by heavy lines in the accompanying figure These are chosen in such a way that, if two treatments are in fact equivalent (so that, in the long run, 50% of the patients' preferences will be in favour of one and 50% in favour of the other), there is a probability of about 0·95 that the zigzag path will end on the middle (V-shaped) boundary, and only 0·05 that it will reach one of the outer boundaries (the two divergent straight lines) In this sense we may say that a path ending on one of the outer boundaries indicates a difference between the treatments which is significant at the 5% level The probabilities stated above are only approximately correct, and exact calculations for the boundaries used here give values of 0·960 and 0·040

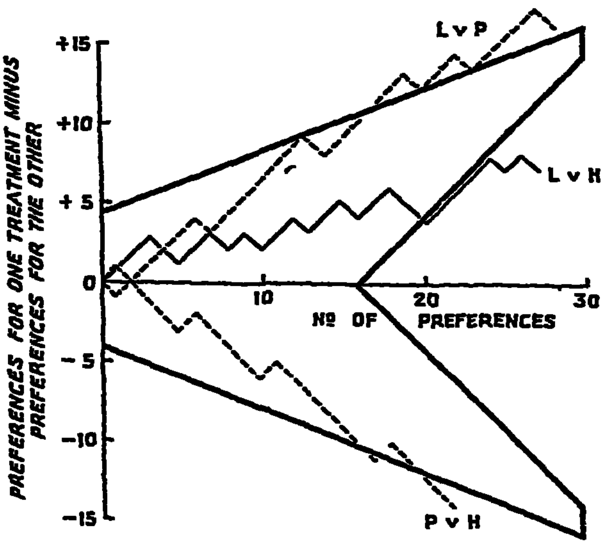

Chart for sequential analysis of results H heroin L, lipect P, placebo In each comparison the path is continued one unit "north-east for a preference for the first-named treatment and one unit south-east for a preference for the second named treatment.

Apart from the choice of the significance level to which the outer boundaries correspond, one is at liberty to choose the maximum of comparisons needed for any pair of treatments During the first few weeks of the present trial we were able to assess the rate at which patients became available for treatment and to make a rough estimate of the proportion of patients giving clear preferences The maximal duration of the trial was determined by other commitments, and we estimated that during this maximal period about 30–35 preferences would be obtained for each pair of treatments Accordingly a restricted sequential procedure, for which the maximum of preferences was 30, was chosen by reference to table v of Armitage (1957), which gives the equations to the boundaries shown in the accompanying figure. According to this table, if one treatment is such an improvement on another that 85% of preferences are in its favour, in a long run of patients, the zigzag path will hit the appropriate outer boundary about 95 times out of 100 Exact calculations confirm that the exact probability of doing this is 0·953 compared with the nominal figure of 0·95

TABLE II—FREQUENCIES OF CLEAR PREFERENCES BETWEEN EACH PAIR OF TREATMENTS ACCORDING TO ORDER OF ADMINISTRATION

Order of administration	Preference for	
	Lipect	Placebo
Lipect before placebo	11	4
Placebo before lipect	11	2
Total	22	6

	Lipect	Heroin
Lipect before heroin	11	2
Heroin before lipect	6	8
Total	17	10

(χ² with continuity correction = 3·41 P = 0·07)

	Placebo	Heroin
Placebo before heroin	2	10
Heroin before placebo	2	8
Total	4	18

The frequencies with which the treatments were placed in various orders of preference are shown in table I, and the sequential paths for each pair of treatments are drawn in the figure The two paths obtained by comparing the two drugs with the placebo both crossed the outer boundaries at the 17th preference, which means that both these comparisons are significant at the 5% level We can attach a rather more precise probability to these results by calculating the probability of reaching, by chance, the observed point on the boundary, or one indicating a more extreme contrast between the two treatments—i e, one further to the left on either outer boundary—if in the long run the two treatments were preferred equally frequently This probability is 0·033 for each comparison of a drug with the placebo

The path obtained by comparing lipect and heroin reached the middle boundary at the 20th preference Again we can calculate the probability of reaching the observed boundary point, or one indicating a sharper contrast between the drugs This probability is 0 36, showing that the slight excess of preferences in favour of lipect could easily be due to chance

If lipect and heroin had both been shown to be better than the placebo at a much earlier stage in the trial, it was intended to omit the placebo so as to concentrate on the comparison of the two drugs As it happened, all three paths approached the boundaries at about the same time A few extra cases were treated after the boundaries had been crossed, and it is clear from the figure that the general trend was confirmed by these additional results

A point of some interest is whether a patient's preference between two treatments depended on the order in which they were given The clear preferences between each pair of treatments are tabulated in table II according to the order in which the treatments were given There is clearly no evidence that order of administration had any effect on the comparison of either drug with the placebo, but there is a suggestion that, for the (presumably harder) choice between lipect and heroin, patients tended to prefer the treatment given first

Discussion

Where it is impossible to make objective measurements of a patient's progress the value of any drug is difficult to assess, but the likely response of patients to drugs will be gauged more reliably by a controlled comparison of the drugs with a placebo than by either experiments on animals or uncontrolled clinical impressions One objection to this type of trial is that the patients may prefer a drug for reasons other than the pharmacological action under test, diamorphine has hypnotic, analgesic, and euphoric properties in addition to relieving cough Possibly diamorphine was preferred to the placebo because of its other properties, but this is unlikely because it was, if anything, less popular than the pholcodine linctus

Another limitation to this, as to any other, type of trial is that the results strictly apply only to the conditions of the trial Thus, it may be said that a *B P C* linctus of diamorphine given in the largest recommended dose is not evidently superior to a pholcodine compound (lipect) when one dose is given at night to the types of patients tested We have no evidence on the effect of other dosages and forms of administration or on the response of different types of patients

The statistical method used in this trial offers certain advantages over previously used methods The boundaries may be drawn on the chart as soon as a decision has been taken on the maximum of patients to be studied, and the level of significance corresponding to the outer boundaries, for which fewer than the maximum are required From this stage, and without further statistical treatment, the results plotted on the chart provide a readily intelligible and graphic account of the trend of the results As soon as a significant difference is observed between one pair of drugs the trial may be stopped or modified so that attention is concentrated on the remaining comparisons

Summary

A controlled clinical trial was undertaken to compare the relative effectiveness in relief of cough of heroin linctus *B P C*, a pholcodine preparation (lipect), and a placebo in 45 patients with chronic cough Each patient received each mixture for two days and placed them in order of preference

A new method of sequential analysis was applied to the results and was found to have certain advantages over methods used previously

At the 5% level of significance there was no evidence of difference between the heroin and pholcodine preparations, but both were more effective than the placebo

We are grateful to Dr R D Green for allowing us to study his patients, and to Dr Gordon Fryers, of Messrs John Wyeth & Brother Ltd, for supplies of lipect

LOCAL TREATMENT OF BURNS AND SCALDS

USING CHLORHEXIDINE

J C GRANT
M B Glasg, F R C S E, F R F P S
SENIOR SURGICAL REGISTRAR

JEAN C FINDLAY
R G N, S C M, R S C N, D T N
SISTER IN CHARGE OF WARDS

ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW

ANTISEPTIC methods of treating burns and scalds are unfashionable, but aseptic and antibiotic methods are not free from complications nor are the results always good In one surgical unit of the Royal Hospital for Sick Children, Glasgow, burns and scalds have been nursed in a small "burns unit" since 1937 Until 1940, the lesions were gently cleansed under sedation or light general anæsthesia and the surface coagulated with tannic acid solutions, silver nitrate, or a mixture of antiseptic dyes "Open methods" of treatment were then adopted and bland dressings, pressure dressings Stannard envelopes, Bunyan bags, local sulphonamides, and local penicillin were all tried, and in the hands of the enthusiast all gave reasonably satisfactory results During this time there were great advances in the general treatment of the burned patient, and inevitably this led to improved results in the local lesion, irrespective of the local treatment adopted The "exposure method" of treatment was rediscovered and was used as a routine procedure for two years, at first with penicillin powder but later without any antibiotic or antiseptic To obviate the need for cleansing the damaged surfaces in the severely burned child dibromopropamidine isethionate cream ('Brulidine') was introduced and was the most popular form of treatment for almost three years Though it is an ideal first aid dressing, dibromopropamidine delays healing and is unsuitable for routine use

During 1955, chlorhexidine (bis *p* chlorophenyl diguanidohexane, 'Hibitane') was first used in the local treatment of burns and scalds The early results were so satisfactory that this antiseptic solution has now supplanted all our previous forms of local treatment

Method

The patients are nursed in three small wards, each with space for three or four cots, grouped round a central corridor which has glass walls The nurses can consequently observe the patients without entering the wards Masks are worn by the nurses and doctors when in the wards No visitors are allowed No woollen blankets, woollen clothing, or fluffy toys are allowed and no toys of any kind from the general ward are brought into the burns wards The furniture, walls, and floors are "damp dusted" twice daily with 1/20 carbolic-acid solution

The patient, after admission to hospital, is sedated and, if necessary, given intravenous fluid The initial dressing of the burn is done without anæsthesia, it is cleansed with 1% cetrimide ('Cetavlon'), rinsed with normal saline, and covered with gauze soaked in 0 5% chlorhexidine solution, a crêpe bandage holds the gauze in position When dressing the burns, the sister or nurse wears rubber gloves, and before attending to the next patient she washes the gloved hands with soap and water, rinses in 1/100 'Dettol' solution, rinses in sterile water, dries, and finally applies 1% chlorhexidine cream to the gloved hands (A no-touch technique is not used) The gauze dressings are resoaked with the chlorhexidine solution twice daily, and twice a week are removed to allow inspection of the lesion and removal of separating sloughs The areas are not left exposed until epithelial cover is complete It is usually possible by the end of the third week to decide where there is whole-skin loss, and these parts of course require grafting

Results

The method has been in use for fourteen months 108 patients have been treated with excellent results Infection is rare The superficial burns heal rapidly by regeneration of the surviving epithelium, and in the deep burns, after separation or removal of the sloughs, a clean granulating surface presents, which is eminently suitable for grafting In the previous twelve months 92 patients had been treated by a variety of methods, and of this group, clinical evidence of infection after admission to hospital had developed in 10 (11%) Of the 108 patients treated by chlorhexidine, clinical evidence of infection developed in only 2 (2%) There are so many variable factors that the two groups are unsuitable for statistical comparison, but the reduced incidence of infection in the second group suggests that chlorhexidine has reduced the incidence of cross-infection

Discussion

Prevention of infection is the fundamental principle in the local treatment of a burn, whether the lesion is superficial or deep If infection arises, it will delay healing and may so destroy the surviving epithelium that a superficial burn becomes a deep burn When a deep burn becomes infected, grafts do not readily take, the patient's stay in hospital is prolonged and he goes home with a poor cosmetic result The method used to prevent infection must not itself damage the tissues or delay healing

The methods used can be divided into three groups—an aseptic technique, an antibiotic technique, and an antiseptic technique

In practice we have found that a rigid *aseptic* technique is impossible The dressings and instruments can be sterilised but not so readily the patient, the patient's attendants, or the dust in the ward It is one thing to use an aseptic technique in an operating theatre for an hour or two with an unconscious patient who does not need a meal or a bowel movement, but quite another to maintain the same technique for three months with a patient who has lost half his skin

The second method using *antibiotics*, accepts that contamination is likely and relies on antibiotics to deal with the organisms before they gain a hold on their host But *Staphylococcus pyogenes* *Streptococcus pyogenes* *Pseudomonas pyocyanea*, and proteus organisms are all common contaminants of a burn, and there is no single antibiotic to which they are all sensitive Furthermore, the *Staph pyogenes* which breed in our hospitals today are seldom sensitive to penicillin or the other antibiotics commonly used, and as each new antibiotic comes into general use resistant strains rapidly appear Hence one cannot rely on local applications of antibiotics for prophylaxis against infection in a burn

Antiseptic methods have been criticised on the grounds that antiseptics, like infection, can destroy the surviving epithelium or inhibit its growth We are satisfied that chlorhexidine deals effectively with bacteria without damage to the surviving epithelium or appreciable delay in healing

Chlorhexidine is an antibacterial agent It is supplied by the manufacturers as 'Hibitane Concentrate 2%' which is a 2% aqueous solution of chlorhexidine diacetate together with a surface active agent This we dilute with three parts of water to produce a 0 5% aqueous solution Bacteriological investigations by Davies et al (1954) have shown that chlorhexidine has a high antibacterial action against a wide range of both gram-positive and gram-negative bacteria and that the activity is maintained in the presence of body-fluids They found no evidence of drug-resistance The manufacturers say that animal wounds heal quite readily when dressed with 1% chlorhexidine solution, they also say that repeated applications of 1% solution to fair skin may eventually give rise to erythema, and they recommend a 0 05% solution for wounds when used as a prophylaxis against infection Calman and Murray (1956) found that a 1% solution produced irritation of the nasal mucosa and conjunctiva, and they recommend that no solution stronger than 0 1% should be used on delicate mucous membranes They have also shown that a 1/40 solution of the 2% concentrate (i e, a 0 05% solution) was effective in killing *Ps pyocyanea* using a two-and-a-half minute contact test between organism and antiseptic in the presence of fresh blood (25% blood broth) *Staph pyogenes*, β-hæmolytic streptococcus, and *Escherichia coli* were killed by even weaker solutions They investigated the antiseptic properties of domiphen bromide ('Bradosol'), 'Dettol,' cetrimide, and benzalkonium chloride ('Roccal'), and found that none could be used in a concentration which gave this wide margin of safety and at the same time was harmless to the tissues We have not encountered irritation of the skin in our patients, though our 0 5% solution is ten times stronger than the solution used in the two-and-a-half minute contact tests It is possible that a weaker solution would be equally effective

We rely on the antibacterial properties of chlorhexidine as our first line of defence against infection, but at the same time take all practical precautions to prevent contamination of the burns

The patients, who are mostly under five years of age, are apprehensive of the twice-daily dressings, though these are not painful Also, the dressings are time-consuming for the nurses But those disadvantages are more than balanced by the absence of infection and the speed of healing

Summary

A method of treating burns using a 0 5% solution of chlorhexidine 'Hibitane' is described It has been used for fourteen months, and 108 patients have been treated

Infection has been rare and the chlorhexidine solution does not destroy the regenerating epithelium or appreciably delay healing

The practical advantages of the method over aseptic and antibiotic methods are discussed

We wish to thank Mr Wallace M Dennison in whose wards the patients were treated, for his encouragement and help

UNIVERSITY OF BIRMINGHAM

To provide a sound basis for protein and electrolyte therapy after the institution of a permanent ileostomy, the loss of fluid and the output of nitrogen, sodium, potassium, and calcium from the ileostomies of 7 patients are reported 6 with ulcerative colitis, and 1 with familial polyposis of the colon (the findings in this case are in keeping with the results of those with colitis)

Methods

Excreta were collected into Rutzen bags, which were emptied at intervals into enamel cans, collections being made in 24-hour lots The volume of each daily collection was measured and adjusted to a suitable quantity for homogenisation by the addition of distilled water Samples were thoroughly homogenised and analysed

For nitrogen two 2 0-ml samples were placed directly into flasks for estimation by a micro-Kjeldahl method For sodium, potassium, and calcium a 10-ml sample was placed in a conical flask, 2 ml of concentrated nitric acid was added, and the mixture was allowed to stand for at least 10 minutes It was then brought to the boil for a few seconds, cooled, made up to 50 ml with distilled water, and filtered (Whatman 544) After the filtrate had been suitably diluted with distilled water, sodium and potassium were estimated with the Eel flame photometer The instrument was graduated over the range 0 2–0 8 mg of sodium or of potassium For calcium 20 ml of the filtrate of the nitric acid digest was neutralised with ammonia and acidified with concentrated hydrochloric acid, and the calcium was precipitated with 2 5% oxalic acid and 20% sodium acetate, overnight standing ensured complete precipitation The precipitate was centrifuged and washed thrice to remove sodium oxalate The calcium content of the precipitate was then determined by titration in acid solution with 0 01 *N* potassium permanganate

The patients had necessarily to be treated according to their needs in respect of fluid and electrolyte restoration since their serious general condition allowed little latitude as regards treatment It was therefore impracticable to maintain an identical fluid and electrolyte intake in all the patients after operation and to follow a strict schedule Usually, however, intravenous fluids alone were administered until the ileostomy began to function, usually about 24–48 hours after operation Fluids by mouth were then permitted 30 ml hourly for the first twelve hours, increasing to 60 ml and then

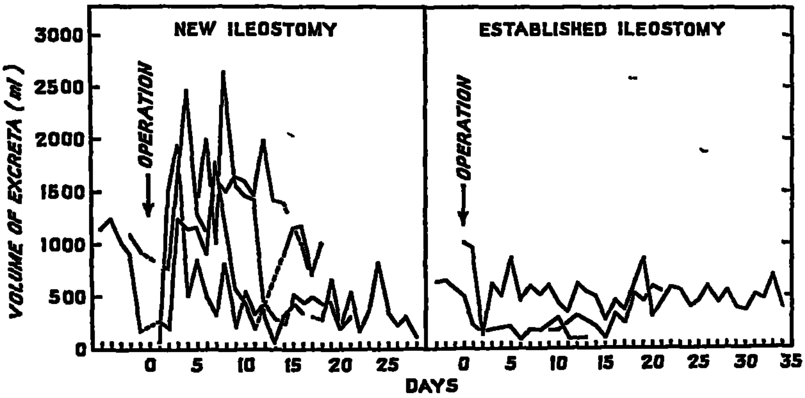

Fig 1—Volume of fluid excreted after institution of ileostomy *new ileostomy*, operation involving the institution of an ileostomy , *established ileostomy*, operation incidental being the removal of the rectum in 3 patients after primary colectomy with establishment of ileostomy 10, 18, and 30 months previously

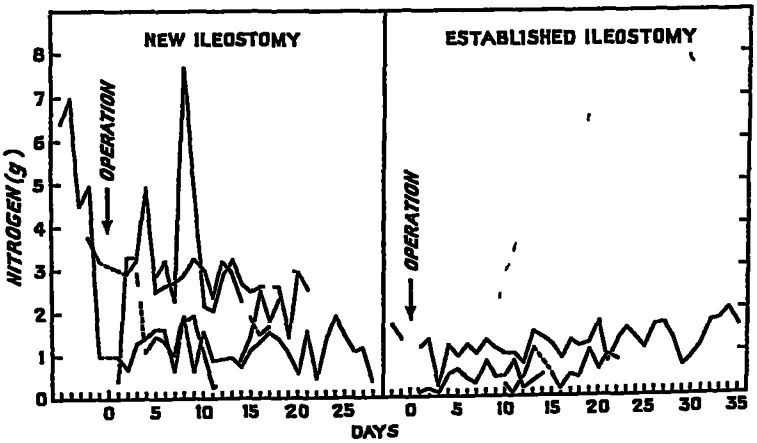

Fig 3—Output of nitrogen

120 ml at 12-hour intervals From about the 5th postoperative day a light diet was taken, increasing to a full diet within 7–10 days It is therefore impossible to present standardised figures from these investigations, we can only report what happened under routine postoperative conditions None of the patients had received corticosteroids

Results

Volume of Fluid

A characteristic feature of most ileostomies was the considerable volume of fluid excreted immediately after the institution of the stoma (fig 1) This averaged 2 litres or more a day during the first postoperative week Occasionally the immediate postoperative output was greater and sometimes considerably less Next it decreased to about 500 ml a day as the excreta thickened The average daily output remained at 500 ml in the established ileostomy, though this sometimes increased after subsequent operations Seldom, however, did it increase to more than 1 litre daily, provided that complications at the stoma—e g, partial obstruction—did not arise The mechanism causing this diminution in output is not clear, alterations in the activity and absorptive capacity of the small bowel are possible factors

During the initial postoperative period a direct correlation existed between the volume of fluid excreted and the quantity of some of the materials measured in the excreta, this relationship being clearest in the case of nitrogen and sodium (fig 2) This cannot be explained by considering the ileum as capable of excreting the various electrolytes only at a constant concentration, because the concentration of sodium became less in the established ileostomy, and that of calcium varied with its intake, as might be expected

Nitrogen

Losses of about 4 g of nitrogen a day were observed immediately after ileostomy, excluding complications, decreasing to 1–2 g in the established case, equivalent to an average daily excretion by normal persons Nitrogen loss was therefore insignificant from the therapeutic aspect Chromatography of exudates from 2 patients indicated that the following amino acids were excreted glycine, alanine, valine, leucine, and arginine Since the total daily nitrogen loss was so small, it seems improbable that the loss of these specific amino acids is significant

A general picture of the nitrogen loss immediately after operation in 4 patients and from ileostomies established for 10, 18, and 30 months is given in fig 3 The operation referred to in the established cases indicates a subsequent procedure in staged excision of the colon and is incidental The high peak of excretion at 8 g on the 8th day after ileostomy in one patient (figs 3 and 4) was associated with severe ileostomy diarrhœa due to pseudomembranous enteritis, which responded rapidly to erythromycin The continued excretion of 3 g daily by one patient (figs 3 and 5) was associated with ileitis secondary to ulcerative colitis (colo ileitis)

In ulcerative colitis more nitrogen may be lost preoperatively per anum than is subsequently lost from the ileostomy In one male patient 7 g of nitrogen (equivalent to 44 g of protein) was lost daily in this way, whereas after operation his nitrogen loss was only 1–2 g daily

Nitrogen-balance studies in 3 patients (fig 6) showed that they were in negative balance for a short period after operation but no longer than patients submitted to operations not involving intestinal fistula After this period they remained in positive balance

Sodium

At first the loss of sodium was considerable (fig 7), being about 200–400 m eq per litre, with no clear evidence of urinary conservation of sodium The total quantities lost at this stage might be greater than the

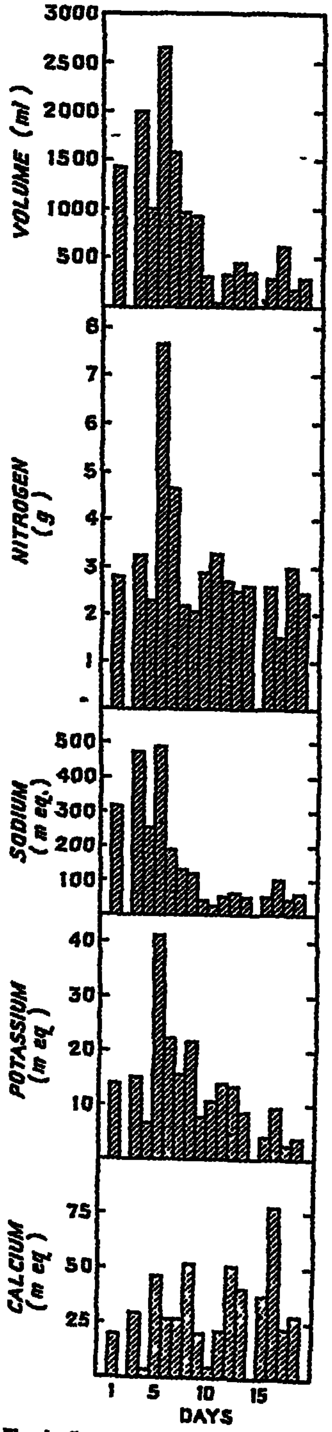

Fig 4—Output from fourth day after primary colectomy

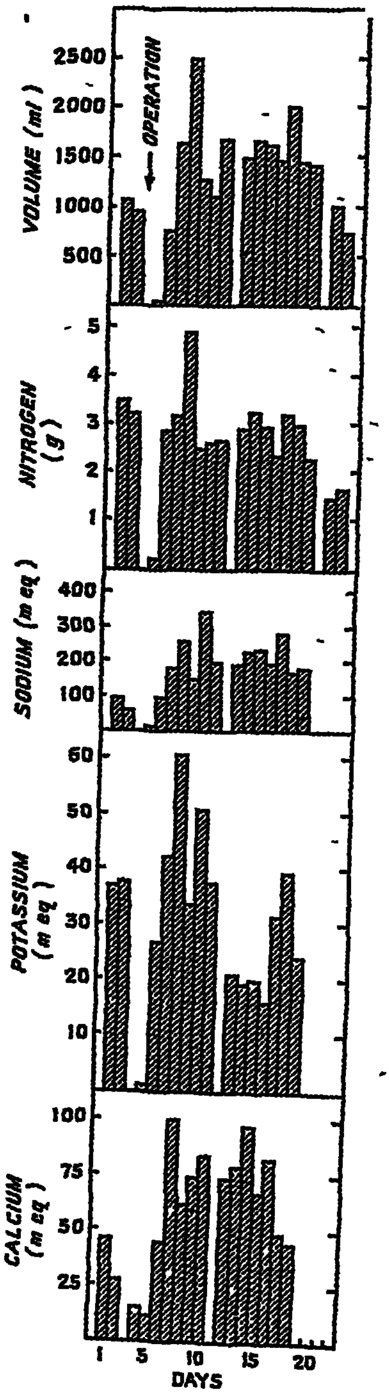

Fig 5—Output from two days before primary colectomy

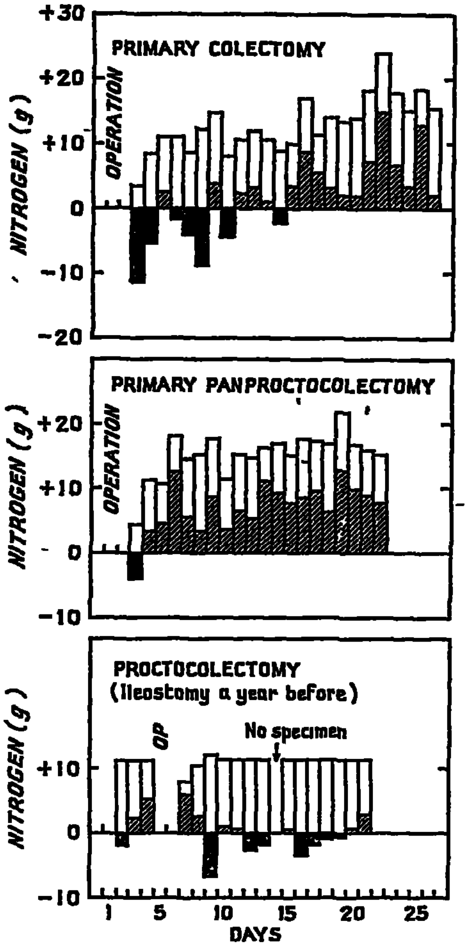

Fig 6—Nitrogen balance in two patients at the establishment of an ileostomy and in one at an operation undertaken a year after establishment of ileostomy

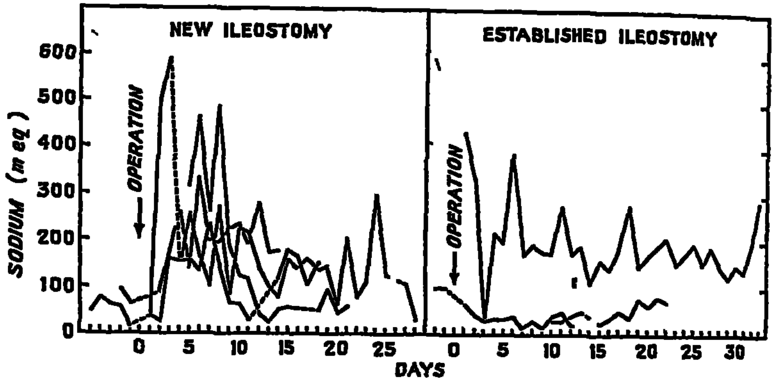

Fig 7—Output of sodium

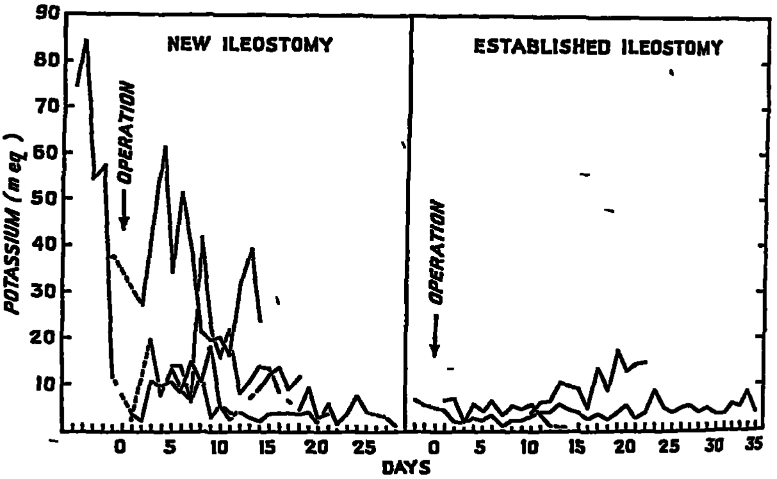

Fig 8—Output of potassium

previous loss in stools resulting from diarrhœa before ileostomy was established. As the excreta from the ileostomy thickened, the rate of loss fell to about 150 m eq per litre. The absolute loss of sodium was therefore great in the immediate postoperative period not only because of a larger volume of excretion but also because of a higher concentration of sodium in the excreta at that stage.

Potassium

In normal circumstances the excretion of potassium hardly exceeds 20 m eq daily—i e, about 10 m eq per litre—a rate which was continued in the established case (fig 8). One patient, who developed severe ileostomy diarrhœa due to pseudomembranous enteritis, had a large loss of sodium and potassium (fig 4); another had a large loss of potassium (fig 5) apparently due to ileal inflammation from persisting colo ileitis. In contrast with the patient with ileostomy diarrhœa, this patient's loss of sodium was less than usual (about 100 m eq per litre), suggesting a reciprocal relationship between sodium and potassium. It seems unlikely that potassium was being excreted in combination with fatty acids as soaps, because excretion was copious immediately after operation, when the intake of fat was nil.

Two preoperative estimations recorded in fig 8 show large losses of potassium (35 and 85 m eq daily) in the stools, these losses being considerably greater than from the subsequent ileostomy.

Calcium

The excretion of calcium was copious (40–100 m eq daily) immediately after ileostomy (figs 2, 4, 5, and 9). There was no associated decrease in excretion when the volume of fluid diminished, presumably because of an increased intake of calcium with more comprehensive diet. The last part of the graph for an established ileostomy (fig 9) indicates that the loss observed with an average normal diet was 30–50 m eq daily (0.5–1.0 g). Daily analysis of the fat in the excreta of 3 patients revealed no direct relationship between the outputs of calcium and fat.

Therapeutic Application

An ileostomy imposes no serious loss of nitrogen and does not disturb the state of balance usually seen after operations. As the ileostomy becomes established, the loss of nitrogen decreases to levels which are average for healthy people who have not undergone operation. Since

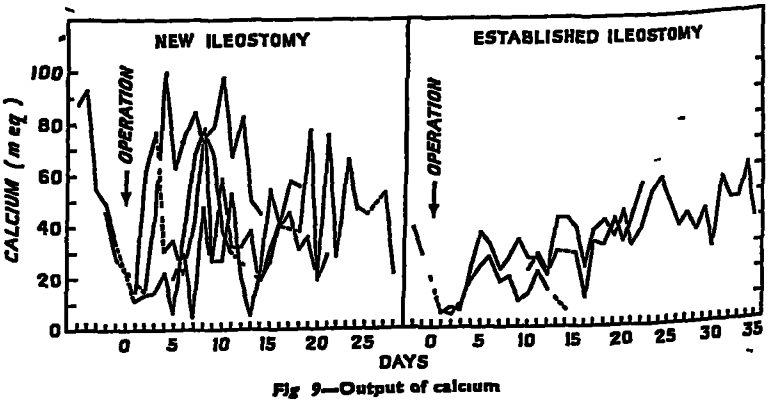

Fig 9—Output of calcium

CHEMISTRY OF ILEOSTOMY EXCRETA

—	Output from ileostomy			
	Recent		Established	
	Per 24 hr	M eq per litre	Per 24 hr	M eq per litre
Volume	1000–3000 ml		200–500 ml	
Nitrogen	2–4 g		1–2 g	
Sodium	200–600 m eq (4–14 g)	200–400	50–200 m eq (1–5 g)	100–200
Potassium	10–20 m eq (0 4–0 8 g)	5–10	5–10 m eq (0 2–0 4 g)	10–20
Calcium	40–100 m eq (1–2 g)	20–50	30–50 m eq (0 5–1 g)	50–100

the total daily loss of nitrogen does not exceed 1–2 g, it seems improbable that the quantity of each specific amino-acid excreted is significant, even though several may be essential for growth The rapid increases in weight seen after ileostomy for ulcerative colitis support this conclusion

The increased volume and the high concentration of sodium in the ileostomy fluid immediately after operation combine to produce a deficit of sodium which may, if not foreseen, induce sudden clinical collapse This is best treated prophylactically by routine intravenous therapy within the first 4 or 5 postoperative days For rule-of-thumb calculation of requirements of sodium it is only necessary to know the daily volume of ileostomy output (a simple ward procedure) and to assume that 300 m eq of salt has been lost with each litre of fluid If the patient suddenly collapses without any obvious surgical complication, especially if the excretion-rate has been persistently high, there is probably salt depletion, which should be treated as an emergency Intravenous double strength saline solution should be given rapidly, when the condition will quickly be overcome, often within half an hour It should also be borne in mind that an increase in the output of fluid from the ileostomy at a later stage from any cause will be accompanied by an increased loss of salt Patients should therefore be advised to take extra salt if ever they have an attack of ileostomy diarrhœa

Whereas loss of sodium is aggravated by ileostomy, loss of potassium is usually corrected thereby (figs 7 and 8) Therefore loss of potassium is mainly a preoperative problem Ileostomy may even have to be expedited for patients in whom it proves impossible otherwise to correct gross loss of potassium from continued diarrhœa Since it is impossible to undertake routine analyses of the potassium in the excreta of all the patients, some loss of potassium may be inferred in patients with ileostomy diarrhœa and in those found at operation to have ileitis In the case complicated by pseudomembranous enteritis the serum potassium level fell from a normal figure of 4 6 to 3 5 m eq per litre in two days In both patients with an excessive output of potassium the loss was about 30 m eq per litre, this figure should be borne in mind when calculating replacement in such patients

The body's reserve of calcium is such that loss immediately after operation causes no immediate concern The continued loss of about 1 g daily from an established ileostomy raises two points, one physiological and one clinical Such a loss is more than a healthy person on an average diet loses in the stools daily (0 4–0 8 g) Is the large bowel in man "inert" as regards calcium metabolism or does it play some part in absorption? It is difficult to believe that the loss of the last 2–3 inches of ileum removed for technical reasons when an ileostomy is undertaken, could explain this difference The clinical significance of this constant loss of calcium can only be judged when balance studies (now being undertaken) are completed Four studies now undertaken including one late in pregnancy, show positive balance

In the accompanying table these observations on the chemistry of ileostomy excreta are presented to facilitate assessment of therapeutic needs It must be emphasised that these figures represent only generalisations because in no two cases were they exactly similar

Summary

The effect of the operation of ileostomy on loss of fluid, nitrogen, sodium, potassium, and calcium in the ileostomy fluid was observed, mostly in patients who had ulcerative colitis

The loss of nitrogen in this disease was reduced by ileostomy

The average daily loss from an established ileostomy had no therapeutic significance for patients on a normal diet

Potassium replacement is therapeutically more important before ileostomy, sodium replacement afterwards About 300 m eq of sodium was lost per litre of excreta from a recently established stoma, and 150 m eq per litre from an established stoma The amount of sodium required for restoration may be calculated from the volume-output on this average

From the established ileostomy calcium was excreted at a rate of about 1 g (50 m eq) daily by patients on a normal average diet

---

Preliminary Communication

RELEASE OF HISTAMINE IN URTICARIA PIGMENTOSA

THE idea that urticaria pigmentosa is a systemic disease with manifestations from different organs, has received considerable support in recent years It has been shown that tissue mast cells may be present in very large numbers in many organs, thus causing a "mastocytosis" Several workers have studied the mastocytomas occurring in dogs

Riley[1] reviewed the question of histamine, heparin, and hyaluronic acid in mast cells

Pernow and Waldenström[2] described a patient with widespread sclerotic foci in the skeleton and a flush resembling that seen after an injection of histamine This patient's urine contained large amounts not only of histamine but also of 5-hydroxytryptamine and *5-hydroxyindole acetic acid* Waldenström et al[3] later gave a detailed description of this case and reported finding increased amounts of histamine in the urine of a patient with typical urticaria pigmentosa

Some months ago I examined a young woman who complained of idiosyncrasy to acetylsalicylic acid

She said that she "nearly died" after taking 0 5 g of acetylsalicylic acid, but "her doctors would not believe" this statement Careful examination showed a few small skin lesions resembling urticaria pigmentosa Dr N Brogren, of the dermatological department, confirmed this clinical diagnosis which was verified on biopsy (Dr G Björkman) Radiographic examination of the skeleton showed definite signs of sclerosis, especially in the vertebræ and pelvis The picture resembled that described by Schorr et al[4] in urticaria pigmentosa Sternal puncture, however, did not reveal any increase in mast cells

The patient was interested in knowing if she could use acetylsalicylic acid, and therefore volunteered to take a test dose Accordingly on Jan 17 she was given 0 25 g of this substance by mouth Her blood pressure remained constant at 120/70 mm Hg for 20 minutes but in the next 20 minutes her systolic pressure fell to 60, her diastolic pressure was not measurable, and her pulse rate rose from about 90 to 150 The systolic blood-pressure was lowest an hour after administration, when it was 30 mm Hg Just before the severe drop in blood pressure the patient felt nauseated and the skin of her face became red She began vomiting intensely Unfortunately the vomitus was not measured until an hour had elapsed The total amount vomited between then and 15 hours later, when vomiting ceased, was 2150 ml The vomitus was strongly acid (pH 2) The patient's temperature, which had been 98 6°F before the test dose, fell to 96 1°F 1½ hours after the tablet was taken After a further hour it rose to 99 6°F, and 3 hours after the tablet was taken it was 101°F The blood pressure slowly rose after intravenous administration of a glucose drip, and after 2 hours was 100/50 mm Hg The pulse rate fell to 80 only after more than 2 days had elapsed After 3 days she was afebrile

---

[1] Riley J F *Lancet* 1951 i 841

[2] Pernow B Waldenström J *Ibid* 1951, ii, 951

[3] Waldenström J Pernow B Silwer H *Acta med scand* 1956 156 73

[4] Schorr S Sagher F Liban E *Acta radiol, Stockh* 1956 46 [illegible]

Obviously this patient is very severely hypersensitive to acetylsalicylic acid Many data seem to indicate that the symptoms may have been caused by liberation of histamine The pronounced circulatory shock with low blood-pressure, high pulse rate, flushed face, and vomiting of enormous amounts of strongly acid gastric contents, and the demonstration of continuous histaminuria all support the diagnosis of histamine liberation by the action of acetylsalicylic acid This substance is not a commonly recognised histamine liberator, but on the other hand the conditions in this case were peculiar the amount of histamine stored in the patient's body may be very large, for the osteosclerotic process is obviously intimately linked with the presence of mast cells I therefore asked three other patients with widespread urticaria pigmentosa whether they had ever observed intolerance of salicylic acid Their answer was No

It therefore seems probable that the supposed action of acetylsalicylic acid as a histamine liberator may be particular to this patient The question of intolerance to acetylsalicylic acid being caused by histamine release and not by a true allergic (antigen antibody) reaction will be discussed in a forthcoming paper B Pernow and H Dunér (personal communication) have demonstrated considerable histaminuria in five further cases of urticaria pigmentosa We are therefore of the opinion that histaminæmia in mastocytosis is a counterpart to hyperhydroxytryptaminæmia in carcinoidosis

Medical Societies

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

THE 77th annual congress of the Ophthalmological Society of the United Kingdom was held in London on April 11–13, with the president, Mr J J HEALY, in the chair Visitors included members of the International Council of Ophthalmology, which met in London on April 10

Intra-ocular Circulation and Hypertension

In his presidential address Mr HEALY described the intra-ocular circulation in arteriosclerosis and hypertension He discussed the ætiological and pathogenic theories of hypertension, which were largely based on the evidence of experimentally produced and secondary hypertension, and he noted that although physiopathological research had made some progress, no definite results had yet emerged Arteriosclerosis might be present as a senile regression in the retinal and choroidal vessels, and essential hypertension might supervene or arise as a separate entity Mr Healy analysed the changes in 200 outpatients' fundi and assessed them with special reference to angiospasm, arteriolosclerosis, and arteriolonecrosis, and he made a plea for greater liaison between physician, ophthalmologist, and pathologist

Simple Glaucoma

The Bowman lecture was instituted by the council of the society in 1883, in recognition of Sir William Bowman's distinguished work in ophthalmology and other branches of medicine and in commemoration of his valuable services to the society, of which he was the first president The 35th lecture was given by Sir STEWART DUKE-ELDER, who spoke on the ætiology of simple glaucoma

Sir Stewart discussed the mechanism of the formation of the aqueous humour in the light of recent biochemical and pathological research, with particular reference to the extensive work carried out under his direction at the Institute of Ophthalmology He then turned to the variations in intra ocular pressure produced especially by peripheral and central nervous stimulation, and he indicated the factors responsible for the instability and range of variation of the intra-ocular pressure characteristic of the glaucomatous eye He traced the development of the initial functional and consequent organic changes with their terminal ischæmic effects upon the structures of the anterior and posterior segments of the eye and the optic nerve, and he examined their respective rôles in the development of clinical simple glaucoma Glaucoma should not be regarded purely as an ocular disease, but rather as a local manifestation of a more general disorder Advances in the scientific aspects had not been accompanied by similar advances in either medical or surgical treatment, which had made little progress during the past twenty years

Congenital Cataract

A symposium on this subject was introduced by Mr J H DOGGART, who said that although some slight opacity was visible in most human lenses, even among the newborn, most of those partial cataracts were harmless and stationary Nevertheless, they could not be dismissed as insignificant because (*a*) they might be misinterpreted and (*b*) they had supplied clues for embryological investigation Differentiation of the various congenital cataracts from other kinds of opacity was impossible without careful study of the living lens

Mr A B NUTT emphasised that the results of surgery for congenital cataract were disappointing and that the prognosis must therefore be guarded Having classified the cases requiring surgical treatment, he gave a brief resume of the operations commonly employed, their complications, and the methods adopted to avoid them He thought that the poor functional results were in many cases due to associated congenital anomalies

Ocular Aspects of Diabetes

Prof G I SCOTT classified the retinal changes of diabetes and discussed their possible ætiology This form of retinopathy could occur in the absence of any evidence of hypertension or arteriosclerosis and its incidence seemed to depend primarily upon the length of time that the patient had suffered from the disease

Dr J D N NABARRO expressed some alarm at the increasing incidence of serious visual defects due to diabetic ocular disease The speed with which vision deteriorated in patients with established retinitis was extremely variable and it was uncertain whether it could be influenced by treatment Strict diabetic control was essential, but there was no evidence that vitamins or sex hormones had any effect Hypophysectomy and pituitary destruction were being undertaken in a few centres, but their value was still uncertain

Dr NORMAN ASHTON dealt with the experimental side of diabetic vascular disease, with special reference to its ocular and renal manifestations He attempted to assess the bearing of experimental findings on the relationship between diabetic retinopathy and glomerulosclerosis

Retinal Detachment

Discussing the rôle of intravitreal vitreous injection in retinal detachment, Mr P McG MOFFATT and Mr C DEE SHAPLAND described the technique for obtaining the donor vitreous and its subsequent injection under pressure into the recipient eye Mr Shapland analysed the results obtained in a small series of his own cases and those of Mr Moffatt

Mr **GEORGE BLACK** criticised present day operations in regard to their effect upon the sclera, such as local necrosis, injury to nerves and blood vessels, and upon anterior structures The effects of diathermy treatment were variable when given through the full thickness of the sclera, and Mr Black described his own method of scleral trap door access to the choroid and its application

Ptosis Operation

Mr H B **STALLARD** advocated the anterior surgical approach to the levator palpebræ superioris, which exposes it in its normal relationship to other structures, reveals any unusual attachment of this muscle to the orbital fascia, allows the separation of any fascial connection with the superior oblique tendon sheath, and permits a greater length of the muscle to be resected and more accurate suturing of the resected muscle to the tarsal plate than other methods of exposure He described a new lidguard for use in this operation and illustrated the technique with a coloured film

Phacolytic Glaucoma

Dr P **SCHOFIELD** gave an account of the association of glaucoma with hypermature cataract Although recognised since 1900, this condition had only recently been defined as a clear cut pathological entity and named "phacolytic glaucoma" From the histological examination of 3 cases Dr Schofield described the pathology and pathogenesis of the condition

Venous Obstruction at the Disc in Chronic Glaucoma

Mr J H **DOBREE** described macroscopic lesions on glaucomatous optic discs, including central vein thrombosis, venous coils, anastomotic vessels, and hæmorrhages at the disc margin These lesions had been seen in a series of 200 cases of chronic glaucoma He discussed the relationship of these vascular changes to other signs of glaucoma such as the prevailing level of tension, cupping, atrophy, and field defects In a control series without tension but with gross arteriosclerotic changes in the vessels, the disc appearances were quite different The main factor determining the onset of the venous lesion was probably the glaucomatous cupping

Foreign-body Detector

Mr M J **ROPER-HALL** described a new electronic instrument which could detect small metallic particles, both magnetic and non magnetic, and assess their chemical and physical properties Two sizes of probe had been made, one $^1/_4$ in and the other $^1/_2$ in, the latter being sensitive to very small metallic fragments at a distance of 15 mm The prototype instrument had already been used to confirm the presence of intra ocular foreign bodies originally detected by X ray examination and localisation, and it had also been used to identify metallic fragments seen on radiographs as magnetic or non magnetic The instrument was insensitive to other metal bodies such as dental fillings and the operating table at distances greater than 3 cm The sensitivity of the probes increased with their size, but so did the range within which other metal bodies affected them (the $^1/_2$ in probe was unaffected by metal bodies at a distance greater than 4 5 cm) Mr Roper Hall said that the instrument was still being developed and that its uses were being extended from ocular to general surgery

Uveitis in Childhood

Mr **JOSEPH MINTON** gave an account of 3 children with severe uveitis, in 1 of whom the full clinical picture of Still s disease developed some time after the original uveitis Cortisone and corticotrophin, and more particularly the new derivatives prednisone and prednisolone, were valuable in treatment A child who had responded indifferently to cortisone was much improved by prednisolone

Ocular Onchocerciasis

Dr F C **RODGER** described an extensive field survey and clinical and experimental work undertaken to determine the types of onchocerciasis in which ocular lesions were most likely To estimate the density of infection he calculated an index which related the degree of infestation and its anatomical distribution over the body with the likelihood of ocular onchocerciasis He found cases in which infectivity was maximum by this standard of examination, and the eyes had actually been invaded, yet there were no ocular lesions This he attributed to an immunity which developed because of infestation in other parts of the body Experimental work with animals has shown conclusively that it was the dead parasite which led to an inflammatory reaction, and nearly all the manifestations of human onchocerciasis were reproduced in the rabbit Dr Rodger found in some cases with posterior-segment lesions, particularly choroidoretinal degeneration, that there was a low individual density figure, and the damage to the tissues might be due to a toxin secreted by the adult worms

Conjunctivitis at Moorfields in 1956

Mr **BARRIE R JONES** had investigated a proportion of the cases presenting at Moorfields Hospital with conjunctivitis during 1956, in order to establish the ætiology of the condition The particular aim was to evaluate the rôle of various viruses in the production of conjunctivitis and keratoconjunctivitis A few infections were due to some of the well-recognised bacterial infections, several cases were associated with infection by adenoviruses, and in others there was evidence of infection by the herpes simplex virus Among other infections seen in association with conjunctivitis were molluscum contagiosum, vaccinia, influenza, and cat scratch fever

---

Reviews of Books

Injuries of the Hand

RONALD FURLONG, F.R C S, assistant orthopædic surgeon, St Thomas's Hospital, London London J & A Churchill 1957 Pp 215 36*s*

Mr Furlong set out to write a manual of practical instruction, and he has written a classic of its kind His style is direct, simple, and vigorous, and if at times his down-to-earth approach is reminiscent of a "do-it-yourself" pamphlet, it is distinguished by the uncommon assumption that those instructed will carry the movement far enough to include thinking One of its unusual feature is that the introductory chapter on anatomy illuminates important relations from clinical experience, rather than condenses them from standard tomes, and a masterly review of general technique answers all the questions that are likely to puzzle the young surgeon (Or almost all what is he to do if, on releasing the tourniquet, circulation does not return ?)

In the sections dealing with injuries to various structures, the perfectionists, the traditionalists, and those whom Mr Furlong calls the "activists" may find much to criticise, but the rest of his readers will readily submit to a guide of such experience and commonsense In the chapter on rehabilitation after tendon injuries he implements his thesis that, whereas the anatomy of the *manus* has changed little from reptilia to man, there has been much specialisation in its cortical control Emphasis is rightly laid not on the crude mechanism of movements (the whole book is happily free from engineering jargon) but on the obliteration of faulty cerebral patterns, and simple but ingenious procedures are described to achieve this

But the masterful "no nonsense" attitude has its perils "If the patient has just eaten a meal, and especially if he has been given a sedative, anæsthetists will make a fuss about giving an anæsthetic to the patient," Mr Furlong remarks drily, and ' take a great deal of convincing that a lacerated hand should be sewn up soon after a meal has been taken " We hope so even Mr Furlong's *haute couture* would be squandered on a dead body

Elaborate attempts at remodelling the thumb also receive abrupt dismissal "In these days of generous compensation for injury patients will not consider reconstructive surgery for loss of a thumb until the sum is awarded then they have no need to" Such pawkiness should perhaps be reserved for morning coffee in sister's office in a book of this kind there is much to be said for giving compensation claims the detailed, serious and practical consideration they deserve

These are but the growing pains of an infant prodigy So much practical wisdom has rarely been packed into the first edition of a book of some 200 pages The 99 illustrations are excellent and few authors have expressed their thanks to the photographic department of their hospital with such good reason In style, presentation, and price we hope this book will set a new fashion for surgical monographs

Battle for the Mind

A Physiology of Conversion and Brain washing WILLIAM SARGANT, M A, M B Camb, F R C P, consultant psychiatrist, St Thomas's Hospital, London London Heinemann 1957 Pp 248 25s

SURPRISING confessions of guilt have been elicited in some countries from political prisoners who seemed to have retained their sanity and who bore no obvious signs of torture Often these have been accompanied by a change of political faith which has outlasted the convert's release from prison These changes in personality have puzzled both doctors and laymen, and the descriptive term "brain-washing" has come to be applied Techniques change, but, as Mr Robert Graves shows in his chapter in Dr Sargant's book, brain-washing was used in ancient times

Dr Sargant was struck by a common thread running through sudden political and religious conversion, war neuroses, possession by Voodoo loa, abreactive techniques and shock treatments in psychiatry, the fantastic confessions of women accused of witchcraft, some of the changes in patients receiving psychoanalytic treatment, and certain confessions obtained by police after intensive questioning (even with the best intentions) He believes that all these changes can be described in terms of pavlovian psychology "Much human behaviour is the result of the conditioned behaviour patterns implanted in the brain, especially in childhood" In humans, as in Pavlov's dogs, these patterns can be destroyed or even reversed by intense nervous stimulation, especially when the resistance has been lowered—for example, by fatigue, fasting, illness, drugs, or endocrine changes The hellfire sermons of Wesley, the inquisitor's threats of torture, the psychoanalyst's insistence on dragging up painful images, the steady drumming and energetic dancing of Voodoo rites, the denial of sleep in a Communist prison, and constant questioning by police, all predispose to a breakdown in resistance If treatment is sufficiently sustained and protracted, nobody but a psychotic can survive unchanged Recent work in North America, not quoted by Dr Sargant, indicates that men starved of stimuli (by being kept in total darkness at a steady temperature and lightly restrained) can be made similarly suggestible their minds create fantasies which they cannot test against reality

This fascinating book is addressed mainly to laymen, but doctors will find it instructive Some will be upset by the mechanistic approach and some will disagree with certain by-the-way conclusions, but they will find it hard to refute Dr Sargant's facts and main conclusions Our legislators would do well to consider the evidence he presents that, even in this country, the confession of a prisoner may have been largely suggested by the examiners It seems questionable whether a prisoner's confession should be allowed as evidence of guilt

A particular merit of the book is that it will provoke a critical approach to evidence of every kind, including that of science

Novant'anni delle Leggi Mendeliane

Edited by Professore LUIGI GEDDA Rome Instituto Gregorio Mendel 1956 Pp 494 £6 5s

IT has been written that in the ten years that Gregory Mendel worked on his peas in the garden of a monastery, he made the greatest discovery in biology that has been made in the past five hundred years This lavishly produced and superbly illustrated book, written in many languages, recalls and honours the discovery of the laws of heredity ninety years ago

It is divided into three parts The first contains a facsimile reproduction of the original manuscript, Mendel's fundamental paper *Versuche uber Pflanzen Hybriden*, which few people have really read and digested, together with a translation into Italian There is also a short biography in Italian, an account of the Mendelian laws in German, and a history of Mendelism in later years in Japanese, with an English summary The second part contains original papers on *general and human* genetics written in honour of Mendel The third consists of fifteen studies of medical genetics

Of the twenty six papers in these parts, written by experts from all over the world, eleven are in English, and summaries in English are appended to the others Harry Harris writes on genes and enzymes in man and W G Lennox on transmission of the cerebral dysrhythmias and seizures in epilepsy An article on the colour of the iris in certain families is especially notable for its illustrations

This, then, is *not* a book of purely historic interest It points to the practical development of the studies to which Mendel gave so great an impetus by launching *them from the start* in the right direction, thanks to his genius and to his modern approach to scientific research Anyone interested in genetics will find this an exciting book

The Organisation of the Cerebral Cortex

D A SHOLL, reader in anatomy in the University of London London Methuen 1956 Pp 125 18s

THE keynote of this monograph is reason, and there is an impressive modesty about the way in which Dr Sholl puts forward his own hypothesis and attempts to evaluate those of others

The book begins with an account of the histological techniques which have been used in analysing the structure of the cerebral cortex, and refers to the work of histologists in assessing the effects of artificially produced lesions in the brain There is a short account of the results of electrical stimulation, but attention is then drawn to the limitation of the cyto architectonic approach to the interpretation of cerebral structure and its function Dr Sholl believes that mathematical and statistical methods are likely to be much more valuable and he gives a clear and concise account of the quantitative analysis of certain aspects of cortical organisation He then goes on to describe the technique of the quantification of neuronal connectivity, which he thinks is most important His work relates very largely to the visual cortex of the cat, but serves to illustrate the relevance and validity of mathematical analysis in human cortical structure

After this outline of structure, Dr Sholl turns to function He is dubious about the views of the cyberneticists and of those who construct machines in the hope of explaining cerebral function Later he states the value of mathematical theories in the interpretation of cortical organisation, and expounds very *clearly* the validity, of the mathematical approach

Even those who disagree with Dr Sholl's views will own that his ideas on cortical structure and function are well worthy of consideration by all interested in neurology, neuro-anatomy, and neurophysiology The main point which he makes is that it is the interconnections of the various types of cells within the cerebral cortex which are important, and it is probable that these interconnections constitute the real clue to the understanding of *cerebral function*

The Labyrinth

Physiology and Functional Tests JOSEPH J FISCHER, M D, clinical professor in otolaryngology, School of Medicine, Tufts University New York and London Grune & Stratton 1956 Pp 206 $6 00

The Inner Ear, written by Fischer and Wolfson, appeared in 1943, and it very soon became a standard work of reference for otologists Dr Fischer has now re-written and modernised it The labyrinth, as here described, includes only that part of the ear which was described by his late chief, Gustav Alexander, as the "*non-acoustic ear*" Dr Fischer describes in great detail the general and applied anatomy and physiology of the equilibrial labyrinth, and the functional tests of vestibular function The newer techniques of caloric testing are included, and such recent rotational tests as the method of cupulometry, described by Egmond and his colleagues in Utrecht, are evaluated Emphasis is also laid on the importance of electrical investigations in the study of labyrinthine function

This classical monograph will remain an invaluable guide to all otologists and neurologists

THE LANCET

LONDON SATURDAY, APRIL 27 1957

Hospital Infection

THE term ' hospital infection ' brings to mind surgery of the pre-Listerian era, with massive gangrene and laudable pus. Yet even now we cannot send a patient to hospital with the confidence that he will suffer no serious infection as a result of being there. Staphylococcal cross-infection is the most usual hazard[1,2], and staphylococcal enteritis is a common and serious complication of antibiotic therapy[3]. In maternity hospitals streptococcal puerperal sepsis is certainly less common than it was, but staphylococcal breast abscesses afflict mothers, and pemphigus and *Escherichia coli* diarrhœa their babies. Hospital tetanus, usually reported as single cases, has just occurred in an outbreak.[4] In a timely review WILLIAMS[5] makes clear two important facts. The first is that as the general frequency of these infections has never been known, progress in their prevention has never been accurately measured; and the second is that ideas on their cause and prevention have fluctuated rather than progressed—belief in airborne infection has been in fashion and out of fashion, and now is in fashion again.

The frequency of hospital infection has often been reported from particular units, but perhaps these reports were prompted by an unusually great amount of infection. This possibility is sometimes mentioned to justify the view that the drastic measures taken to quell outbreaks are unnecessary in the ordinary way. It seems that before any real progress can be made the precise frequency of hospital infection of all types in medical, surgical, and obstetric units up and down the country must be ascertained. We believe that the results of such an inquiry would be surprising. (MELENEY[6] records that a senior surgeon, asked to estimate the frequency of wound infection in his unit, said ' two per cent.' Investigation showed it to be 14%.) We also believe that the time has come for a new appraisal of methods of preventing hospital infection. Usually the effect of such methods is guessed, and the guesses are often influenced by personal prejudice. Those who conscientiously try to measure the effects find that the measurement must be made over a long time, during which new factors may come into play. Much effort would be saved if the environmental and other factors that could serve as indicators of the risk of infection were established by detailed studies. Once the relation between each factor and the frequency of infection was determined a preventive measure could be rapidly evaluated by *determining its effect on the relevant environmental factor*—not by a long and inaccurate comparison of infection-rates ' before " and " after '.

The factors worth investigating are many. Methods for ridding the human nose of *Staphylococcus aureus* have been described, but it has yet to be shown that infections with this organism depend on, rather than control, the carrier-rate in the surrounding population. The infection of surgical wounds is sometimes attributed to unsatisfactory methods of treating the patient's skin before an operation. But before new ways of doing this are devised, and before judgment is passed on the old ones, would it not be best to find out whether skin carriers of pathogenic organisms are especially liable to wound infection?[2] Expensive and complex ventilation-plants and ultraviolet-light barriers are devised for operating-theatres and hospital wards; but the relationship between the number of airborne organisms in these places and the frequency of wound and chest infection or infantile diarrhœa has not yet been defined.

The definition of relationships such as these calls for painstaking observation and ingenious statistical method. Both of these have been applied in two recent studies from the Air Hygiene Laboratory at Colindale. In the first WILLIAMS et al.[7] examined the air in school classrooms and related the numbers of bacteria of different types to factors such as temperature, humidity, ventilation, and various kinds of activity. In a second study bacterial counts on the air were correlated with the occurrence of infections that might be airborne.[8] The organisms counted were not those causing the diseases under consideration; indeed this cannot be done for some pathogenic organisms or for viruses. Most use was made of estimations of the general bacterial population and of *Streptococcus salivarius* in the air. The use of these organisms as indicators of air contamination is comparable to the examination of drinking-water for fæcal coliforms rather than for typhoid bacilli. The *Strep. salivarius* count was significantly related to the risk of classroom transfer of measles, and can be reasonably used as an index of this risk. The general bacterial counts were related to the incidence of certain respiratory diseases (and not to that of measles) but this relationship was such that it could not be used as a reliable index of the risk. The Colindale workers are careful to point out that bacterial contamination of the air is not necessarily related to the incidence of these diseases as cause and effect, since each might depend on another and unknown factor.

All this work was done in classrooms; the results cannot be applied to hospital wards and the infections that arise in them. But we are not here concerned so much with results as with the demonstration that scientific techniques can reveal the relation of environment to infection. The methods used by WILLIAMS and his colleagues could now well be applied to problems of air hygiene in hospitals, and we hope that they will be. Different bacteriological but similar statistical methods should help to answer some of the questions that we have mentioned.

Even those who disagree with Dr Sholl's views will own that his ideas on cortical structure and function are well worthy of consideration by all interested in neurology, neuro-anatomy, and neurophysiology The main point which he makes is that it is the interconnections *of the various types* of cells within the cerebral cortex which are important, and it is probable that these interconnections constitute the real clue to the understanding of cerebral function

The Labyrinth

Physiology and Functional Tests JOSEPH J FISCHER M D, clinical professor in otolaryngology, School of Medicine, Tufts University New York and London Grune & Stratton 1956 Pp 206 $6 00

The Inner Ear, written by Fischer and Wolfson, appeared in 1943, and it very soon became a standard work of reference for otologists Dr *Fischer has now* re-written and modernised it The labyrinth, as here described, includes only that part of the ear which was described by his late chief, Gustav Alexander, as the "non-acoustic ear" Dr Fischer describes in great detail the general and applied anatomy and physiology of the equilibrial labyrinth, and the functional tests of vestibular function The newer techniques of caloric testing are included, and such recent rotational tests as the method of cupulometry, described by Egmond and his colleagues in Utrecht, are evaluated Emphasis is *also laid* on the importance of electrical investigations in the study of labyrinthine function

This classical monograph will remain an invaluable guide to all otologists and neurologists et al[16] have pointed out Yet problems remain of 9 patients in whom **TELFORD** divided the lumbar splanchnic supply, 6 remained well three to seven years later[1] Why was sympathetic denervation of the chronically obstructed but otherwise normal bowel sometimes effective?

Day Hospitals

THOSE who visit a mental hospital for the first time are usually surprised to find that only a few of the patients—between 1% and 5% perhaps—are treated in bed Indeed, if the space used by patients in the traditional mental hospital is analysed according to its purpose, recreation and sleeping are found to take the largest share, with occupation next and specific treatment last This division of function was dictated by the need for custodial care the hospital was the permanent home of some 80% of its inmates, and it aimed at providing within its boundaries a facsimile of life outside But the recent advance of curative (or at least palliative) psychiatry has had a profound effect on the function of mental hospitals and on the types of patient who enter them Though the long-stay patients still form about 80% of those resident at any one time, they are a diminishing proportion of those admitted The average length of stay of all classes of discharged patients is now about seven months and is shortening, and nearly half are discharged within two months of admission Because so many can thus be returned to their homes in a matter of weeks, the question arises whether the complex social organisation of a hospital is needed for their care The day hospitals now being established are an attempt to find an alternative, and at least one positive advantage can be claimed for them, in that often, if not usually, the patient benefits by maintaining daily contact with his home and normal interests while he is having treatment

Day hospitals are hard to classify, because most of them have grown up in response to specific needs, and no two are alike In an industrial area, for example, the object may be to cater for the patient who could attend a clinic for treatment but has to be admitted as an inpatient because all his family go out to work and he is too depressed to be alone all day Those provided for old people are also in a special class Nevertheless, two main kinds of day hospital may be recognised among those at present in action in this country (1) those attached to a mental hospital or bedded unit of some kind and accepting only patients who would otherwise need inpatient care, and (2) independent units, usually combined with outpatient clinics and prepared to treat all but the most disturbed patients The latter kind have been criticised on the one hand as being no more than elaborate outpatient clinics (and, as such, uneconomical), and on the other because, in attempting to deal with all comers unsupported by inpatient facilities they are said to be accepting undue risks But if we look at the Maudsley and Bromley day hospitals described in these columns on April 6 and in our present issue, they seem to satisfy—though in different ways and for different reasons—both the test of need and the test of economy they offer a special sort of service, and they are economical compared with other forms of care The Maudsley day hospital is one of those designed for a selected class of patient who would otherwise need inpatient attention The running costs are low because it uses the parent hospital's facilities for feeding, occupation, and physical treatment Because of its existence, at least twenty beds in the parent hospital are freed for other cases, but patients attending the day hospital can still be admitted immediately to the main hospital if emergency arises The Bromley day hospital is a multiple-purpose unit, but, unlike some others, it does not undertake physical treatment, and does not therefore need a nursing staff and elaborate equipment Though it is independent and cannot draw on the resources of a hospital, it is inexpensive But perhaps its most interesting characteristic is the use it is making of voluntary help and its association with other social agencies

These Maudsley and Bromley day hospitals show the extremes of the range of function of this kind of unit One clearly belongs to the hospital service and derives its usefulness from the closeness of its association with an inpatient establishment The other is an offshoot of the social life of a community It is still in the experimental stage, and, though opinions may differ as to its advantage for the patient who would normally receive full hospital care, it may serve as a prototype for local health authorities in providing for the aftercare of patients who have been discharged

Annotations

5% AND AFTER

UNDER the Government's "interim adjustment," described in our Parliamentary columns this week, all consultants and senior hospital medical officers will have a 5% rise in remuneration from May 1 This will, of course, give the largest money increases to the specialists who have the largest N H S incomes, and, since the main purpose of the interim adjustment should have been to give help where this is most acutely needed, we regret that the £1,200,000 provided for specialists does so little for the junior who (unlike many of his elders) is gaining little or nothing from the Budget's surtax changes Perhaps more attention can be paid to need in deciding on the distribution of the 5% rise for general practitioners This adds £2,500,000 to the total sum available to them as a group, and the Minister of Health is prepared to discuss with their representatives the best way of dividing it

The special representative meeting of the British Medical Association called for next Wednesday may have to decide, among other things, whether acceptance of this interim award is compatible with the "planned withdrawal" from the National Health Service which the B M A council has proposed as a means of exercising pressure on the Government We have already stated our opinion that the only kind of withdrawal they would in fact be justified in considering is permanent resignation from the service[1]—the possibilities of which could be explored while accepting the interim adjustment and cooperating with the Royal Commission The policy of direct action has won some victories, and, for all we know, it might still win more But their cost, though intangible is likely to outweigh the gain, and we earnestly hope that the representatives will now feel that they can safely take the longer view

Hirschsprung's Disease

"MEGACOLON" is an inapt name for Hirschsprung's disease, since dilatation and thickening of part of the colon is simply the outcome of chronic obstruction in normal bowel due to immotility of abnormal bowel beyond, yet for many years this misnomer conditioned our approach to the disease Thus it is not long since the condition was explained on the hypothesis that autonomic imbalance in favour of the sympathetic nervous system caused atonia and dilatation, both being enhanced by sympathetic increase of sphincteric tone, and accordingly patients were treated by lumbar sympathectomy[1] or lumbar ganglionic block[2] "That sympathetic overaction is the cause of the condition is confirmed by the fact that appropriate sympathectomy leads to a relief of the condition"[3] Though the conception was wrong the trail was nevertheless leading in the right direction, for it was postulated that O'BEIRNE's "sphincter" at the recto sigmoid junction was most commonly affected by the spasm[1], and, as we now know, this is often the proximal end of the aganglionic segment causing the obstruction HURST noticed that the rectum was not appreciably dilated or only slightly so in comparison with the pelvic colon above it[4] At that time TELFORD[1] and PATERSON ROSS,[5] both exponents of sympathectomy, doubted whether overaction of the sympathetic system could be the cause, and felt that the operation might succeed by restoring balance in a disorder due to parasympathetic defect at the level of the dilated bowel To PATERSON ROSS it seemed possible that vagal and sacral autonomic nerves might fail to meet in these cases, leaving an area without parasympathetic supply Perhaps the misnomer was responsible for the fact that evidence of defects in the myenteric plexus beyond the dilated areas was so long ignored In 1920 DALLA VALLE[6] first noticed such evidence, and in 1927 CAMERON[7] found the ganglia replaced by inflammatory cells, both observed that the plexuses were normal in the dilated areas, and others reported likewise[8] In 1948 SWENSON[9] switched the surgical attack to the segment of bowel beyond the dilatation, on radiological evidence of "spasm" in 20 cases of Hirschsprung's disease at the lower limit of the area of dilatation he resected the rectum in 3 children, performing a colo anal anastomosis of the pull-through type which he had already practised in dogs The following year BODIAN and his associates[10] reported their neurohistological studies of 15 cases, revealing that the parasympathetic system is indeed at fault, since its ganglia are absent from the narrow bowel and a small adjoining segment of dilated colon Further studies by SWENSON[11] of peristalsis showed strong waves in the hypertrophied colon, but none in the distal segment

1948-49 is therefore the *annus mirabilis* in the treatment of Hirschsprung's disease, because of the work of SWENSON and of BODIAN therapeutic effort came to be based on facts instead of speculation Surgery acquired a new growing-point requiring its confines to be determined in terms of indications, of management, and of pre- and post-operative care These are outlined by Mr WYLLIE elsewhere in this issue A series of 152 patients have been operated upon at Great Ormond Street by DENIS BROWNE's modification of SWENSON's operation by which resection is deferred until the bowel has been delivered through the anus 102 patients are now over 3 years old, and 55 are normal in every way, in the remainder constipation and incontinence, temporary but sometimes protracted, have been the chief imperfections These difficulties have arisen partly because the inability to develop the normal habit of defæcation before operation impedes its institution subsequently, and partly because the operation robs the patient of the sensory area in the lower rectum (SWENSON reported that each of 150 patients had done well after operation apart from occasional incontinence immediately afterwards, except for 3 children aged 2-3 no recourse had had to be made to laxatives or enemas[12]) WYLLIE's report is perhaps less important for the assurance it gives of the effectiveness of rectosigmoidectomy than for its guidance on the management of cases, the indications for operation, the feasibility of one-stage operation with the appreciation of the need to act early, and in some cases the urgent need to relieve obstruction by colostomy[13]

Biopsy per anum is a recent diagnostic advance It is not always easy to be sure that a patient with "megacolon" in fact has Hirschsprung's disease Hitherto the diagnosis has rested on the radiographic demonstration of the cone at the junction of hypertrophied with abnormal bowel (indeed WYLLIE points out that in order to reveal this it is necessary to undertake barium enemas during a period of constipation and not after the bowel has been cleared by washouts) This cone is not always visible—for instance, when a short low segment is affected, or after defunctioning by a colostomy undertaken previously to relieve obstruction SWENSON[14] makes an incision *in the* anal canal extending upwards along the columns of Morgagni to obtain a specimen of the internal sphincter and circular muscle-fibres above it, together with the longitudinal fibres externally, the absence of ganglion cells between these layers can then be determined BILL et al[15] have found the method of wider value, for they have seen cases of constipation regarded on clinical and radiological grounds as Hirschsprung's disease but proved by biopsy to have a normal ganglionated myenteric plexus The Great Ormond Street group have carried a biopsy a stage further by using frozen sections at operation to determine where normal intestine ceases and abnormal begins, so ensuring complete excision and obviating recurrence The aganglionic area may extend even as far as the small intestine, as WYLLIE and BOWDEN

of the time at least at less than peak efficiency. Some may be dazed others hyperactive and furiously energetic, but in either case their judgment and performance is below their best. Williams and Rayner suggest that in relief work there is a compelling urge to act and a tendency to think that every act must be completed as quickly as possible, and "this inner compulsion may lead to action which is more rapid than necessary even in the emergency situation." The sense of urgency is often accompanied by an intense concentration on the task in hand, however trivial, to the exclusion of all else. Victims and helpers "seem to operate within a field of narrowed perception or limited awareness." The ability to recognise changing patterns and to anticipate future developments declines, and many may lose their capacity for adapting (or abandoning) familiar responses however inappropriate they have become. Doctors often face a conflict of rôles. The effort needed for leaving behind victims at hand in order to fulfil tasks assigned to them in distant hospitals may be immense. In major disasters, especially when they work without rest, many develop a profound and debilitating feeling of guilt. They may realise that they simply cannot help all those who need their help, but their repeated, conscious assertion that they are doing all they can is a sign of mental fatigue (though unfortunately they will be the last to recognise it as such). Against this the emotional "inoculation" of training and experience affords a high degree of protection, but this is possible only with planning and advance selection of personnel.

The need for such planning was underlined by the Harrow railway disaster in 1952.[4] The Ministry of Health then suggested improvements in organisation[5], and the Sutton Coldfield disaster was successfully dealt with under the scheme agreed for Birmingham.[6] Certainly the country is better prepared for civilian disasters than it was five years ago; but it may still be doubted whether in each area the plans fully integrate the considerable resources of the Armed Forces with those of the civilian services.[5]

HYPERTHYROIDISM IN CHILDREN

FEW pædiatricians have much experience of treating hyperthyroidism; for only 1–2·5% of all cases of Graves's disease are found in children.[7] It is especially important that such children be correctly treated, for prolonged hypothyroidism from over-treatment retards growth, and conversely under-treatment may result in accelerated growth.[8] There is an almost bewildering array of remedies.

In congenital hyperthyroidism iodine is probably the drug of choice. The stimulus to over-production of thyroid hormone by the infant seems to be derived from the mother and regresses gradually after birth. Iodine rapidly controls the hyperthyroidism, and the effect usually lasts until the natural remission develops, but some infants may require additional anti-thyroid drugs, and Lewis and MacGregor[9] have described a case treated with carbimazole and potassium iodide.

In juvenile hyperthyroidism iodine cannot be expected to bring about permanent remission. There is universal reluctance to administer radioactive iodine to young people, and external irradiation of the thyroid gland, formerly favoured,[10] has rightly fallen into disuse. (Of 28 young patients with carcinoma of the thyroid 10 had received irradiation of the thymus in infancy.[11])

On the whole, the results of subtotal thyroidectomy are not encouraging. In children this operation is especially difficult; for the risks of damage to the recurrent laryngeal nerves and to the parathyroid glands are greater, and the effects of postoperative œdema and hæmorrhage more serious than in adults. Moreover, it is hard to decide how much of the gland to excise: to remove too little is to court recurrence, and to remove too much is to condemn the child to thyroid medication for life. Van Wyk et al.[12] describe 4 surgically treated cases: 1 child died after operation, and the remaining 3 became hypothyroid; in 1 hypoparathyroidism developed. Kunstadter and Stein's[13] series contained 5 surgically treated cases with the following formidable complications: hypothyroidism (3 cases), hypoparathyroidism (1), obesity (2), retarded growth (1), and severe keloid scar (1). In each of 5 other children under their care who were treated by thyroidectomy some endocrine complication ensued. Crawford,[14] who advocates surgical treatment, noted no recurrence of the disease in 18 cases so treated, but of 10 children followed for more than two years only half could dispense with substitution therapy after twelve months. McClintock et al.[15] treated 45 of their 50 patients surgically, but they now favour selection based on definite criteria. We cannot dispute that partial thyroidectomy has a place in the treatment of the hyperthyroid child, but it should be reserved for those who fail to respond to proper medical treatment and those with large goitres.

The arguments for and against a conservative regime lose their sharpness in view of the modern dictum that no hyperthyroid patient should undergo any operation until he has been made euthyroid by medical means. The decision, therefore, may safely be postponed for several months. Long courses of medical treatment may have bad emotional effects in adults, but most children do not resent medical attention provided that admission to hospital and unpleasant special investigations are avoided. With methimazole or carbimazole undesirable side-effects are less common than with thiouracil or its derivatives. Using the thiouracil group of drugs and methimazole, Kunstadter and Stein[13] achieved remissions of more than two years in 8 patients, 6 of whom remained well for over five years. They estimate that medical treatment is successful in 65–85% of children. A similar remission-rate was obtained by Allen et al.[10] In these series exophthalmos did not get worse, and after an initial increase in size the thyroid gland regressed eventually. In some cases the regression could be hastened by the addition of desiccated thyroid *U.S.P.* 15–30 mg. daily, to inhibit the production of pituitary thyrotropin.[16] It seems clear that the longer treatment is continued, the greater the likelihood of a permanent cure.

The results of carbimazole therapy in juvenile hyperthyroidism have not yet been reported. This drug is almost certainly safer than the thiouracil derivatives[17]; but it is not entirely free from side-effects, and fatal agranulocytosis in an adult has been reported.[18] The pædiatrician therefore looks hopefully to potassium perchlorate. In doses of 200–800 mg. daily in adults this was found to be virtually free from side effects and clinically effective in nearly all cases by Godley and Stanbury[19] and Morgans and Trotter.[20] But the response was slower than with other anti-thyroid drugs, and where this is likely to be a serious drawback it would be reasonable to combine this treatment initially with carbimazole and to use perchlorate alone for maintenance when the patient is

GRAFTS AND AORTOGRAPHY

In the past five years the indications for vessel grafting have been broadened and in many centres the demand for homografts has outrun the supply This has led to considerable investigation of various synthetic substitutes, of which at least eight are in use 'Vinyon-N,' 'Orlon,' 'Terylene,' 'Ivalon' (polyvinyl alcohol), 'Teflon,' 'Fortisan,' and stainless steel As any one worker's experience must necessarily be limited, the Society for Vascular Surgery in 1955 appointed a distinguished committee to investigate contemporary opinion among vascular surgeons Of sixty seven surgeons who replied to their questionary twenty-nine stated that synthetic materials were not used at all in their clinics [1] In those centres using synthetic material the aorta had been grafted 256 times with a failure-rate of only 0 7% peripheral arteries had been grafted 160 times with a 37% failure-rate

The failures with aortic prostheses were due to disruption, thrombosis, hæmorrhage, or infection all occurred in the late follow-up period after the grafts had initially functioned satisfactorily This experience compares favourably with that from homografts Like homographs these synthetic materials produce a moderate inflammatory reaction and eventually (with the possible exception of ivalon) become bonded to the neighbouring tissues by fibroblastic ingrowth The final fate of these grafts has yet to be determined, but from studies after two years degenerative changes seem likelier to develop in homografts Synthetic materials are more difficult to apply and they may cause considerable bleeding through the interstices when the clamp is released, but pre-clotting, finer weaves, or chemical treatment will probably overcome this difficulty This evidence is encouraging, but neither the aorta nor the large intra abdominal vessels are good proving grounds for vascular prostheses, for the amount of connective tissue laid down as a new intima never encroaches seriously on the large lumens Grafting a peripheral artery is a much more stringent test, and the failure rate of 37% at centres widely experienced in vascular surgery probably does not reflect the general rate The difficulties in the periphery are the small bore of the artery, the length of the graft, and the crossing of flexion sites Of the available synthetic substances crimpled nylon tubes and terylene taffeta have been most successful in peripheral arteries, and terylene and teflon in the aorta Nylon loses much of its tensile strength within twelve to twenty four months, and the failures were most numerous with ivalon

Whether direct surgery should be inevitably preceded by aortography is discussed by Crawford et al [2] This valuable diagnostic method has been criticised because of its complications, among which are pain, hæmorrhage, aortic thrombosis, embolism, organ infarctions, dissecting aneurysm, spinal-cord damage, and allergic manifestations Crawford et al review their experience with 300 aortograms, complications were few, and even these can be largely attributed to errors in selection of patients, in choice and dose of contrast medium, and in technique of injection Multiple punctures must be avoided, and Crawford et al. believe that the aorta should be pierced only once, well above its major abdominal branches, to avoid flooding these with a high concentration of organic iodide Only 15–25 ml of contrast material is manually injected, after a preliminary test injection has determined the location of the needle These workers conclude that in the great majority of vascular diseases involving the abdominal aorta there is no need to undertake preliminary aortography In a series of 280 aneurysms of the abdominal aorta treated surgically, only 1[illegible] involved the segment of aorta from which the major visceral arteries arise Crawford et al therefore prefer to assess the aneurysm by direct exposure at operation, for, as they point out, involvement of the renal and other vessels no longer constitutes a contra indication to resection and grafting Of a further 215 cases of occlusive atherosclerotic aortic disease, half had incomplete and half complete occlusion In patients with complete aortic occlusion, they always found, distal to the major vessel block, patent arterial segments which were suitable for anastomosis In fact Crawford et al would limit aortography to the occasional patient in whom the diagnosis of aortic disease is in doubt—for instance, the fat person with a suspected but impalpable aneurysm, or the patient with partial aortic occlusion and palpable femoral pulses Possibly aortography, which since its introduction in 1929 has helped so much in defining the anatomical problem before the surgeon, is now becoming redundant because widening clinical experience has shown the constancy and predictability of the arterial disease processes Certainly the doctrine of Crawford et al brings hope of relief to overburdened X-ray departments

PLANNING FOR DISASTER

Planning for disasters is an awesome task Their site, their moment of impact, and their force cannot be fore seen Modern industrial communities have means of mass relief on a great scale, but the proper use of these potentialities demands a high degree of preparedness and skill Williams and Rayner [1] emphasise that the medical services can be among those most severely hampered by the disruption of normal organisation, and they insist that plans for emergency medical services must therefore be integrated with the general plans for disaster relief The problem is at heart logistical how to get the right services and the right victims together in the right place at the right time For this Williams and Rayner regard three things as essential.

First, good *two way communication* is necessary not only for mobilising relief but also for bringing order into the initial and unplanned mass assault and for maintaining it as circumstances change The second main need is transport Inefficient traffic control affects the medical services mainly by delaying the distribution of patients to suitable hospitals At hospitals close to the disaster area which receive most of the injured and become overloaded, little more than first aid can be given to those most urgently in need of specialist help If they could have been removed to more distant (and perhaps better equipped) hospitals, the waiting time there—and often the total interval between injury and definitive surgery—would have been considerably less Sorting, or *triage*, the "key to management of victims of disaster," [2] can be effective only when transport is adequate and free to move Thirdly it must be known where and in what quantities resources can be found, and how these are to be distributed In peace time disasters over supply may cause embarrassment or even obstruction (During the 1953 flood in Holland, the help of a surgeon and some cattle fodder were repeatedly requested in nation wide broadcasts, and next day, over miles of angry water, six surgeons and ten tons of cattle fodder arrived [3])

Research in America has shown that in disasters few people—and very few doctors—lose their head or break down in the usual sense of the word, but many (possibly a substantial majority) work, for part of the time at least at less than peak efficiency. Some may be dazed, others hyperactive and furiously energetic, but in either case their judgment and performance is below their best. Williams and Rayner suggest that in relief work there is a compelling urge to act and a tendency to think that every act must be completed as quickly as possible, and "this inner compulsion may lead to action which is more rapid than necessary even in the emergency situation." The sense of urgency is often accompanied by an intense concentration on the task in hand, however trivial, to the exclusion of all else: victims and helpers "seem to operate within a field of narrowed perception or limited awareness." The ability to recognise changing patterns and to anticipate future developments declines, and many may lose their capacity for adapting (or abandoning) familiar responses however inappropriate they have become. Doctors often face a conflict of rôles. The effort needed for leaving behind victims at hand in order to fulfil tasks assigned to them in distant hospitals may be immense. In major disasters, especially when they work without rest, many develop a profound and debilitating feeling of guilt. They may realise that they simply cannot help all those who need their help, but their repeated, conscious assertion that they are doing all they can is a sign of mental fatigue (though unfortunately they will be the last to recognise it as such). Against this the emotional "inoculation" of training and experience affords a high degree of protection, but this is possible only with planning and advance selection of personnel.

The need for such planning was underlined by the Harrow railway disaster in 1952.[4] The Ministry of Health then suggested improvements in organisation,[5] and the Sutton Coldfield disaster was successfully dealt with under the scheme agreed for Birmingham.[6] Certainly the country is better prepared for civilian disasters than it was five years ago; but it may still be doubted whether in each area the plans fully integrate the considerable resources of the Armed Forces with those of the civilian services.[5]

HYPERTHYROIDISM IN CHILDREN

FEW pædiatricians have much experience of treating hyperthyroidism, for only 1–2·5% of all cases of Graves's disease are found in children.[7] It is especially important that such children be correctly treated, for prolonged hypothyroidism from over-treatment retards growth and, conversely, under-treatment may result in accelerated growth.[8] There is an almost bewildering array of remedies.

In congenital hyperthyroidism iodine is probably the drug of choice. The stimulus to over-production of thyroid hormone by the infant seems to be derived from the mother and regresses gradually after birth. Iodine rapidly controls the hyperthyroidism, and the effect usually lasts until the natural remission develops, but some infants may require additional anti-thyroid drugs, and Lewis and MacGregor[9] have described a case treated with carbimazole and potassium iodide.

In juvenile hyperthyroidism iodine cannot be expected to bring about permanent remission. There is universal reluctance to administer radioactive iodine to young people, and external irradiation of the thyroid gland, formerly favoured,[10] has rightly fallen into disuse. (Of 28 young patients with carcinoma of the thyroid 10 had received irradiation of the thymus in infancy.[11])

On the whole the results of subtotal thyroidectomy are not encouraging. In children this operation is especially difficult; for the risks of damage to the recurrent laryngeal nerves and to the parathyroid glands are greater, and the effects of postoperative œdema and hæmorrhage more serious, than in adults. Moreover, it is hard to decide how much of the gland to excise: to remove too little is to court recurrence, and to remove too much is to condemn the child to thyroid medication for life. Van Wyk et al.[12] describe 4 surgically treated cases: 1 child died after operation, and the remaining 3 became hypothyroid, in 1 hypoparathyroidism developed. Kunstadter and Stein's[13] series contained 5 surgically treated cases with the following formidable complications: hypothyroidism (3 cases), hypoparathyroidism (1), obesity (2), retarded growth (1), and severe keloid scar (1). In each of 5 other children under their care who were treated by thyroidectomy some endocrine complication ensued. Crawford,[14] who advocates surgical treatment, noted no recurrence of the disease in 18 cases so treated, but of 10 children followed for more than two years only half could dispense with substitution therapy after twelve months. McClintock et al.[15] treated 45 of their 50 patients surgically, but they now favour selection based on definite criteria. We cannot dispute that partial thyroidectomy has a place in the treatment of the hyperthyroid child, but it should be reserved for those who fail to respond to proper medical treatment and those with large goitres.

The arguments for and against a conservative regime lose their sharpness in view of the modern dictum that no hyperthyroid patient should undergo any operation until he has been made euthyroid by medical means. The decision, therefore, may safely be postponed for several months. THE BOMB TESTS

BEFORE long a certain number of thermonuclear weapons of unknown power will be exploded in the Pacific—unless the British Government change their mind Unhappily, they show no sign of doing so or of taking urgent action to secure international control of nuclear bomb tests In his reply[1] to the Japanese prime minister, Mr Macmillan again declared his confidence in the safety of the forthcoming tests, but added nothing new in the way of reassuring facts The most gloom-provoking passage in his letter is that in which he speaks of working for the abolition of nuclear tests "at the appropriate stage" in a scheme of general disarmament Mr Macmillan's statements after his return from the Bermuda conference suggested to many people that a full scale fusion bomb—the so called "dirty" bomb that releases enormous quantities of radioactive isotopes—would not be exploded in the tests on Christmas Island[2], but nothing more has been officially said about "clean" bombs, and fears remain Further alarm has been caused by the recent fusillade of Russian explosions, which were presumably big ones since they were detected

Whatever bombs they plan to fire, the Government again find themselves following a much criticised course, and they must be listening carefully and uneasily to every opinion, scientific and non scientific, from at home and abroad Mr Macmillan has been unresponsive to the appeals from Japan and elsewhere, but we hope he will be more impressed by the sombre statement of the Atomic Scientists' Association, which appears on p 878 This careful analysis of the situation concerning strontium 90 shows plainly how feeble is the case of those who argue against the immediate abandonment of all further nuclear explosions The only safe assumption is that the damage produced is proportional to the radiation received, and that there is no threshold dose On this assumption, the committee of the Atomic Scientists' Association calculate that a hydrogen bomb of Bikini type, exploded high up, may eventually produce bone cancers in 1000 people for every million tons of T N T of equivalent explosive power It has been estimated that bombs hitherto exploded are equivalent to 50 million tons, so far as strontium 90 fallout is concerned Thus, the damage may well have been done for thousands of people

Proposals for nuclear disarmament[3] have been put before the United Nations disarmament subcommittee by Mr Stassen, Russia avows her eagerness to call a halt to testing, and from many sides there come signs that people and governments realise that something must be done very quickly[4] The British Government should acknowledge that the situation is a new and deadly one in which it has become an urgent duty to negotiate an agreement with all speed, so that tests can stop very soon and not at some vague "appropriate stage" Perhaps no single act could do more to bring an agreement nearer than the abandonment of the British tests

RETIREMENT OF PROFESSOR MEULENGRACHT

NOBODY has done more to enhance Denmark's high reputation in the field of medicine than Prof Einar Meulengracht, who retires next week from the staff of Bispebjerg Hospital, Copenhagen, after thirty three years as a chief physician

Meulengracht's original work has been mainly in hæmatology and gastro enterology In his youth he worked out a simple colorimetric method for estimating the degree of jaundice, and this icteric index was widely used for many years His investigations of chronic hereditary hæmolytic jaundice are fundamental, and he has contributed much to the understanding of pernicious anæmia and its treatment, notably through his studies of the pylorus in pigs (In these columns a fortnight ago he and two colleagues showed that the response to administration of heterologous intrinsic factor contained in hog pyloric mucosa differs from that to administration of homologous intrinsic factor) But he is best known for his revolutionary work on bleeding peptic ulcer Abandoning the usual treatment by starvation, he found that mortality was reduced, and recovery hastened, by feeding the patient amply from the start

Through the years many British and other foreign doctors have visited Meulengracht's department and observed his outstanding ability as a clinician and teacher On ward rounds he shows himself as a clear thinker who abjures speculation on the one hand and displays of erudition on the other His style is concise, his manner friendly, quizzical, and urbane It seems highly improbable that, at a spirited 70, this man will relax and enjoy the peaceful retirement he has earned

WELLCOME TRUST

The Wellcome trustees have announced the following benefactions

(1) £95,000 to the University of Birmingham as a contribution to the cost of building an extension to the clinical research block at the Queen Elizabeth Hospital The extension, which will substantially increase the accommodation for research workers in the university departments of medicine and surgery, will be known as the "Wellcome Wing"

(2) Up to £11,000 to the Middlesex Hospital Medical School for the cost of providing an extension, to be known as the "Wellcome Annexe," to the Institute of Clinical Research, *Hanson Street, London,* W 1

(3) £10,000 to the Christian Medical College Hospital, Vellore, South India, for the cost of setting up a metabolic research unit and maintaining it for five years *The* unit is to be used in the first instance for a study of fat metabolism in relation to tropical sprue

(4) The trustees have also agreed to purchase the following items of special equipment for indefinite loan to research centres (*a*) a nuclear magnetic resonance spectrometer (costing approximately £17,000), for the department of chemistry, University College, London, and (*b*) a photo electric spectropolarimeter (costing approximately £3000), for the department of biochemistry, Postgraduate Medical School of London

THE LANCET AIR-MAIL EDITION

We now print a small proportion of our weekly issue on India paper for transmission to distant countries by air The subscription rates for one year, inclusive of air mail postage, are

AUSTRALIA AND NEW ZEALAND £13 13 0 (sterling)
UNITED STATES, CANADA, SOUTH AFRICA, AND INDIA £11 11 0 (sterling)
OTHER COUNTRIES *Quotations on request*

MENTAL illnesses encroach not only on the life of the patient but also on the lives of his family and close friends These encroachments can be greater than those of even severe physical illness, which is socially far more acceptable to the general public and to many hospital workers Today we are beginning to recognise that some of the important roots of psychological upset are to be found within the community Social circumstances influence the unfolding of character, and are as important as genes, and probably more so than orthodox education More than any other factor perhaps, social isolation drives the patient to eccentricity or to a frank behaviour disorder Not only does social isolation evoke mental illness, but the illness, which is unacceptable to the community, heightens isolation Mental hospitals are by no means a complete answer to this problem, for the patient remains an embarrassment to his family, quite apart from the burden which he imposes on society

As a result of this state of affairs, psychiatric departments of general hospitals, unattached to a mental hospital, have often more patients than they can cope with During the past ten years we have been trying to run a psychiatric unit of the kind which offers not only diagnosis, but also treatment outside a mental hospital. Our difficulties and our attempts to solve them have led, one step at a time, to the formation of the Stepping Stones Club

THE TOWN

Bromley, in Kent, was originally a satellite town of London, it is now virtually a suburb It is a mixed community which still has some fairly wealthy members There is some light industry, but it is mainly a dormitory town and the main shopping centre for the surrounding housing estates There are many churches an orchestra, choral societies, a repertory theatre, an amateur dramatic society, and many other cultural and recreational groups The town has a strong civic sense

THE HOSPITAL

Bromley Hospital was founded by the local community as a voluntary cottage hospital Before the start of the National Health Service it had become a general hospital, with visiting consultants from the London teaching hospitals, the general practitioner specialists who had originally staffed it still take an active part in clinical work and administration

Outpatient psychiatry was started in 1945, one of the three present psychiatrists holding a monthly session By 1948 three psychiatrists took 13 sessions with the help of a full time and a part-time psychiatric social worker (P S W), a part time educational psychologist, a part time nurse, and a full time secretary, and larger premises were being sought Once the N H S started there were more urgent priorities and the psychiatric work continued in a consulting room, an office and a waiting room curtained off from the chiropody or orthoptic clinics Two other consulting rooms were sometimes available

A pioneer occupational-therapy unit had been started in the hospital grounds in 1946 About half the patients were physically disabled and half were referred from the psychiatric clinic The results, particularly in paraphrenics whom we had assumed it would not be possible to treat outside a mental hospital, were surprisingly good The success appeared to be due to the patience and skill of the occupational therapists and to the mixture of disablements within the department Both staff and patients came to understand that mental illness is as severe a disablement as the traumatic and disease processes also being treated there Both groups of patients were doing creative work; the psychiatric patient's first sign of recovery was usually an offer to help another patient who seemed to him more seriously disabled than himself

VOLUNTARY HELP

Lectures were given to local organisations from the first days of the clinic Doctors and P S W s in this way met their colleagues, and also parent-teacher associations, church groups, and many other clubs The Townswomen's Guild started branches in Bromley at the request of the clinic, and the lectures began to break down the prejudices about mental illness and to bring offers of help often from ex-patients and their relatives. Church members found accommodation for the homeless the Friends of Bromley Hospital helped patients both financially and by visiting elderly lonely patients The W V S provided meals-on-wheels, and the British Red Cross handicraft instructors and escorts Many of these groups welcomed patients and ex-patients, bridging their initial shyness with great understanding It became clear that this sort of help often sped the patient's recovery In 1951 members of the Board of Control suggested that the hospital should apply for a grant to help to house and formalise these activities The suggestion was premature but provided a focus for planning

During 1953–54 the senior P S W visited many of the people who had offered to help in the work and discussed with them the possibility of doing so It was pointed out that volunteers should be interested and in sympathy with the work, unafraid of mental illness, and prepared to enter into normal social relations with patients Helpers who were skilled in some art or craft, such as music, handicraft, painting cooking or acting, would make a valuable contribution by joining in such activities with the patients It was also pointed out that helpers would have to attend regularly, whether once a week or only once a year, and that they would either have to provide a deputy or give due notice when they could not come

The response to these discussions was so encouraging that a meeting was called with the help of the Friends of Bromley Hospital Members of the hospital management committee and the hospital administrative officers attended The Bromley League of Churches, the Doctors Christian Union, and the Trades Council all sent observers and the Stepping Stones Club was formed The elected committee started groups alongside the existing drama and discussion groups, they strongly advocated an approach being made to the Board of Control to ask how financial help could be obtained Groups were conducted in the clinic, in private houses, and in church halls

Last year the King Edward's Hospital Fund for London allocated the H M C £18,000 to buy, convert, and furnish a house After many vicissitudes a house has now been bought which will house both the clinic and the club It should be opened within three months

FROM THE CLINIC

New patients are sent by general practitioners, school medical officers, and hospital staff at the rate of over 300 annually A third of these are children under 15, but a quarter of the adults are seen as emergencies on domiciliary visits Fortunately these seldom need admission to hospital, though 8–10% of the adult patients are sent to local mental hospitals, to the Bromley Hospital, or to neurosis centres

Many acute patients can be maintained outside hospital by daily visiting during the first week, and the general practitioner and P S W s together, sometimes with the domiciliary nurse, undertake this responsibility In these circumstances the patient is seen at least twice weekly by a member of the clinic staff Relatives have proved extremely cooperative, these methods often avoid the break-up of the family which can be a tragedy where there are young children As soon as possible patients are persuaded to attend the occupational-therapy department We do not insist on compulsory daily attendance, but the patient who is given something to occupy him for even a small part of each day can be much more easily kept at home with relatives

As soon as they are well enough patients are encouraged to attend one of the evening groups During the day many come to read in the small waiting-room of the clinic This has been so helpful that in the new house the Friends of Bromley Hospital intend to provide a daily hostess who will relieve the clerical and other staff

Mental breakdown in older patients is often accompanied by severe malnutrition or major physical disease These patients are often investigated as inpatients in the psychiatric beds of Bromley Hospital

In the outpatient clinic each new patient is usually seen for three quarters of an hour, and old patients are allotted half an hour When possible each patient has ten psychotherapeutic sessions, and one or more home visits from the P S W We gave up the use of physical treatments in 1952 though we refer any patient who asks for it to a suitable clinic

TO THE CLUB

During the past year, the club's membership has grown from 200 to 300, of whom 100 are helpers, including the clinic staff All active members take part in different club activities without distinction as to whether or not they are patients This rule, the most fundamental rule of the club, has been extended to visitors

At the moment ten groups meet regularly, most of them weekly, usually in the evening at a time when both housewives and patients who have returned to work can attend most easily The numbers in each group fluctuate between 7 and 25 The two original groups —the children's play club and the mothers' discussion group, which were run concurrently—have had to be temporarily abandoned until our new house is ready Each year the club gives four parties for its less mobile or more scattered members The groups contribute to these parties in turn and ex-members often attend

Since the first meeting the direction and control of clinical treatment have remained in the hands of the psychiatric clinic staff, but the organisation of the club has been entirely the responsibility of the voluntary body This body has shown a high degree of social responsibility The club committee consists of a representative of each group or type of group, representatives of the hospital management committee, and representatives of the Friends of Bromley Hospital The clinic staff attend whenever they are able, but have no vote The club is a registered charity and has been helped financially by the League of Hospital Friends, this, together with the subscriptions given voluntarily by its members, has met all its expenses

The activities are determined by the interests of the members Any four or five people who wish to start a new group are encouraged to meet and form a nucleus to which patients can be directed Arrangements are fluid, and voluntary workers are not persuaded to remain in the club once their interest has waned The work is enjoyable but demanding, and freshness of approach is essential In so far as possible voluntary workers are not allowed to overwork

Helpers are recruited from all classes of society, in contradistinction to psychiatrists and social workers who are normally recruited from a narrow stratum The education of the technical worker is long, it leads him away from ordinary everyday ideas and language An intelligent voluntary worker or ex patient, on the other hand, who shares with the patient his background and language, can at times help him, particularly when he is acutely ill and confused, more than the trained worker The trained worker, however, can guide and educate the voluntary worker and provide support in times of stress Hence a trained worker at present attends each discussion group where the more serious problems emerge Other groups are visited when possible and their leaders are given special training and support

The activities of the club are designed to avoid social isolation during the acute stage of mental illness to break it down if it has become established, and to provide a link through which the patient can resume a full life within the community It is too early to estimate the impact of this kind of social therapeutic work on psychological techniques So far the results are encouraging

---

STRONTIUM HAZARDS

Statement by Atomic Scientists' Association

IN view of the widespread concern about radiation hazards, and particularly the effect of radioactive strontium produced in nuclear-weapon tests, the council of the Atomic Scientists' Association appointed a committee, under the chairmanship of Prof Joseph Rotblat, to study the problem, and to follow up the implications of last year's Medical Research Council report in the light of more recent information What follows is based on the committee's report issued last week

When an H bomb is exploded at a high altitude, and in an area in which there are no inhabitants—as is said to be the case with the forthcoming British tests—there is very little likelihood of immediate injury to people, or of substantial local contamination of the oceans, even if a large amount of radioactivity is produced in the explosion This radioactivity would be taken up into the upper regions of the atmosphere from where it would spread all over the globe and gradually descend to the ground over a period of some years By that time only the long lived radioactive products of the bomb would remain, and it is the possible effects of these that are of concern

If H bomb tests continue at the present rate, the dose of radiation to the reproductive organs, which may cause damage to future generations, has been estimated in the M R C report to be of the order of 1% of that resulting from the natural level of radiations Of greater import, however, is the damage which may result to the present generation, mainly from one radioactive substance—strontium 90 This substance enters into food, chiefly in vegetables and dairy products, and it accumulates in the human body in the bones, where it remains for a long time Depending on the assumptions made about the distribution of strontium in bone, it is calculated that by the year 1970 the radiation dose to bone from all the tests carried out up to the autumn of 1956 will range from 9% to 45% of the dose received from all natural sources, including the radium which is normally present in bone

It is known that radioactive substances concentrated in the bone may give rise to bone cancers and other damage, and that the irradiation of bone marrow may result in leukæmia The induction of bone cancers by the action of strontium 90 in the bone has been demonstrated in animals, in human beings the same effect has been observed with radium, which in some ways behaves like strontium In all these cases, however, the amounts of radioactivity present in the bone were far greater than those that are likely to accrue from H-bomb tests. The question then arises how to apply these findings to very small doses. There is here a fundamental difficulty, in that the relationship between the damage produced and the amount of radiation is not known. If this relationship is such that there exists a threshold dose below which cancer cannot be induced, then it can reasonably be inferred that the small amount of strontium 90 which will accumulate in bone from the current H-bomb tests would not result in any harm. If, however, the number of additional bone tumours resulting from radiation is directly proportional to the dose, then even a very small dose will give rise to a small but definite probability of bone cancer. This means that in a very large population a certain number of people would contract this disease as the result of their having a small amount of strontium 90 in their bones.

The evidence is as yet inconclusive. Some animal experiments have been interpreted as indicating the existence of a threshold dose. On the other hand, in man, the occurrence of leukæmia caused by radiation suggests a simple proportional relationship. Unfortunately the question cannot be settled by experiment in a short period of time, nor is there strong guidance from theory. There is one theory of the origin of cancer (that it is due to somatic point mutation) which implies a proportional relationship. Where the effects of strontium 90 are concerned the authorities responsible for the M.R.C. report appear to be inclined towards the proportional hypothesis, for they state: "On the whole the experiments seem in favour of a proportionality between the frequency of tumours produced in a given length of time and the amount of radioactive material in the body even at low dose levels."

If the proportional relationship is accepted, it is then possible to make a rough estimate of the number of bone cancers which may result from a given H-bomb test. Calculations show that an H bomb of the type tested at Bikini in 1954, if exploded high in the atmosphere, may eventually produce bone cancers in 1000 people for every million tons of T.N.T. of equivalent explosive power. (It has been stated that bombs hitherto exploded were equivalent, in aggregate, to 50 million tons, in so far as their strontium 90 fall out is concerned.) These 1000 casualties would be spread all over the world and occur in the course of several decades. A somewhat larger number of people might suffer other bone changes, possibly without manifesting any clinical symptoms. There is also the probability of a number of cases of leukæmia resulting, but there are not enough data to estimate this number. At the same time, these casualties, although large in absolute number, represent only a fraction of those due to the natural level of radioactivity; there would be no way of distinguishing one from the other.

If other types of nuclear weapons were exploded, the number of casulaties would vary in direct relation to the amount of fission products released into the upper atmosphere.

In giving these estimates it must be emphasised again that, apart from the considerable margin of error due to lack of adequate data, they are based on the as yet unproved hypothesis of a proportional relationship applying to very small doses. From this point of view they represent the most pessimistic approach. On the other hand, if this hypothesis is correct, then the figures may be an underestimate of the damage, since they do not allow for the radiation dose in children before or after birth. Children are known to take up much larger quantities of strontium than adults, and the likelihood of producing radiation damage in them is probably much greater for the same amount of radiation.

An appendix to the report sets out a method of estimating strontium 90 hazard, assuming a linear relationship between bone tumour *formation* and *dose*:

(1) The measurements of the ^{90}Sr content in human bone in this country, carried out by workers of the U.K. Atomic Energy Authority,[1] show that by the beginning of 1956 the average amount in all age groups from 10 years upwards, was about 0·2 strontium units (S.U.) (1 S.U. $=10^{-12}$ curies of ^{90}Sr per g. of calcium).

(2) If this figure is applied to the data of the world survey of strontium 90 made by the Lamont group,[2] the committee conclude that the ^{90}Sr concentration resulting from all the tests carried out up to the autumn of 1956 will in 1970 amount to about 4 S.U. This value is in agreement with the estimate of 4–10 S.U. made by Libby[3] for the U.S.A.

(3) The total fission yield from the tests carried out up to the autumn of 1956 is estimated[2] to be equivalent to 50 megatons. For one nominal high yield weapon (as defined in the Indian government's document[4]: 20 megatons with high fission yield) exploded high in the atmosphere, one may therefore expect a concentration in bone of 1·6 S.U.

(4) From Hasterlik's survey[5] of bone sarcoma in people with a radium burden, the committee estimate that 0·1 micro curie of radium yields about 0·5% probability of bone sarcoma. (A factor of 2 has been allowed for the possible admixture of mesothorium with the radium.)

(5) Since 0·1 microcurie of radium is accepted[6] *to be* equivalent to 1000 S.U., applying this probability value to the population of the whole world ($2·5\times10^{9}$ people), the number of bone sarcomas from one nominal high yield nuclear test may amount to 20,000–all over the world ($2·5\times10^{9}\times0·5\times10^{-2}\times1·6\times10^{-3}$).

(6) The radium normally contained in the body and the external radiation from natural sources deliver to the bone a dose equivalent to 45 S.U., or 9 S.U., if one allows for the non uniform concentration of strontium in bone.[7] This means that the dose rate from strontium in bone will amount to 4/45 or 4/9 of that due to the natural background.

The report is signed by Prof. H. S. W. Massey, F.R.S., president of the association, and Mr. H. R. Allan, PH.D., hon. general secretary.

Public Health

The Glasgow Campaign

A FULL report of the Glasgow mass-radiography campaign is not yet to hand, but it seems that for once the organisers cannot complain of a poor public response. In the first few weeks it was impossible to be radiographed without standing in a queue. A total of 710,838 people were radiographed. On the closing day hundreds were still queuing at midnight; the staff and equipment were overworked (the tubes became overheated and had to be cooled with wet towels); 46,077 people attended, which is a world record for one day.

Preliminary examination has disclosed 8074 cases of pulmonary tuberculosis needing observation or treatment. The figures per cent. are 0·2 of active disease, 0·7 of doubtful active disease, and 0·19 of healed disease. On April 29 the campaign will shift to other parts of Scotland, heralded by runners carrying torches.

The Early M.O.H.

Few people have known much about the doctors who were working as medical officers of health between the appointment of John Simon to the City of London (with the passing of the Public Health Act of 1848) and the appointment of other London medical officers of health in 1855. Prof. C. Fraser Brockington's researches into the events of that period were published last year in the *Medical Officer*, and have now been reprinted as a small book.[8] This includes the text of Dr. S. E. Piper's report on Darlington in 1851 (in which he decried the overcrowding and ubiquitous smallpox, and called for

better sewage and scavenging, not only for their immediate benefits but also for the example they would set in cleanliness) and appendices giving the duties of officers of health in 1851, the dates of constitution of local boards of health, and biographical details of the medical officers of health of 1848–55

Tuberculosis in Europe

The death-rate from tuberculosis is declining generally in Europe, according to a statistical report published by the World Health Organisation Thus between 1950 and 1955 the crude death-rate per 100,000 population fell from 36 4 to 14 6 in England and Wales, from 13 8 to 6 3 in Denmark, from 143 6 to 63 0 in Portugal, from 39 4 to 20 1 in Western Germany, and from 78 5 to about 16 7 in Eastern Germany Deaths from respiratory tuberculosis are now commoner in people over 60

But in 1954 the disease still caused 0 9% of deaths in Denmark and Iceland, 1 6% in Britain, and 5 6% in Portugal

Parliament

Interim Adjustment of Remuneration

On April 16 the **Prime Minister** made the following statement in the House of Commons

Before the Royal Commission was appointed I explained that its appointment did not preclude an interim adjustment in advance of and without prejudice to its recommendations An adjustment was made in the remuneration of the junior hospital staff, both medical and dental, at the beginning of this month, when their remuneration was increased by 10% In announcing this increase, I said that we were considering what should be done by way of an interim adjustment for the other doctors and dentists covered by the Commission's terms of reference

The Government have now decided to increase the basic remuneration of senior hospital medical and dental staff including consultants and specialists and all dentists engaged in general dental services by 5% from May 1, and from the same date to add 5% to the aggregate net remuneration of general practitioners—that is, remuneration after the deduction of practice expenses We propose to consult representatives of the profession as to the best method of distributing this sum between individual practitioners

In the meantime, the Royal Commission has been asked to regard its work as a matter of urgency and has, in fact, already, I understand, held six meetings I hope that the letters I have exchanged with the then president of the Royal College of Physicians, together with the statement issued by the chairman of the Royal Commission, will reassure those who have expressed concern about the terms of reference

I hope now that all concerned will turn their thoughts to the task of working out a satisfactory basis for future remuneration, and for keeping it under review

Dr **Edith Summerskill** What was the basis used to arrive at this award? Why has this decision been made in an arbitrary fashion without negotiation with the doctors? Why has the decision been made without any consideration of the findings of the Royal Commission? Will the right hon Gentleman say whether the distribution from the central pool will be similar to that made in 1952? The **Prime Minister** It was always stated by the Government that we intended to make an interim award while the Commission was sitting The 10% was given to the junior staff and now 5% is given to the general body The reason this procedure is adopted is that the present dispute is on a matter of the interpretation of the Spens report Therefore, there could not be any agreed basis for negotiation in the ordinary way The object of the Commission, which is really an independent body, is to find and recommend what should be the basis of remuneration both now and in the future As to the method of calculation, I do not know whether it is similar to that in 1952 In the case of the 10%, it is as I have already stated In the case of the 5% to certain senior hospital medical and dental staffs and the dentists engaged in the general service, and of the doctors in ordinary practice, it is by adding to the aggregate net remuneration, and then we propose to consult the doctors' organisations as to the best method of distributing this money

Mr **Hugh Gaitskell** Can the Prime Minister say how much this will cost? The **Prime Minister** The senior medical staff, about £1,200,000 The general medical practitioners, £2,500,000 The general dental practitioners £1,200,000, to which I should add a 10% increase to the junior hospital staff, which is £900,000 Mrs **Jeger** Cannot the Prime Minister give us a better explanation of the basis of these calculations? Is he saying that he thought up 10% in his sleep one night, and that on another night he thought up 5%? What is the arithmetic behind a suggestion which provides the same increase for highly paid consultants as for the humbler and overworked general practitioners? The **Prime Minister** As I have explained, we appointed a Royal Commission because, in this case, there is a disagreement as to what should be the whole basis for calculating remunerations both now and in the future I hope that this independent body, with terms of reference which I have explained to be very wide, will reach that basis Meanwhile, since the Commission must take a considerable time—a substantial time—to make its report, it was thought right to make this advance I hope and believe that it will be regarded on the whole as equitable and reasonable

Mr **Arthur Woodburn** Can the right hon Gentleman say what steps are to be taken to see that fairness is done to the assistants? In some parts of the country quite a lot of empire building is going on among doctors and assistants The public would like to know that the assistants were to get proper treatment under these arrangements The **Prime Minister** No doubt my colleague the Minister of Health will take that point into account in consultation with the doctors' representatives as to the methods of distribution

Mr **Marcus Lipton** How does the Prime Minister expect employers and workers to accept the principle of collective bargaining if he ignores this principle in dealing with the doctors' increment of pay? Is he aware that this contempt for established machinery is regarded as a very grave injustice by the medical profession? The **Prime Minister** I do not think that that is really quite fair It is a prerequisite of any arbitration that there should be common agreement on what the arbitration has to be about The difficulty here is disagreement about the interpretation of the Spens report The most practical way—I think there is general opinion in the country supporting this—is to get the most independent body we can—and I think we have in the Royal Commission a very good independent body—to try to reach an agreed basis from which, in future, these adjustments can be made without difficulty

Dr **Donald Johnson** May I ask the Prime Minister whether he will press, or ask the Minister of Health to press upon the medical organisation the necessity of bearing in mind in distributing this 5%, that there is quite serious concern at the differences in remuneration among various practitioners within the same service, and that it will give this point very serious attention in the distribution of the extra sum? The **Prime Minister** Yes, Sir

Mr **Arthur Blenkinsop** Can the Prime Minister assure us that at last the Minister of Health will have real power to carry out negotiations in this matter, and that he will not only take account of the position of assistants but of the position of doctors with smaller lists and will try to make a constructive settlement that will help to reduce the large lists of the richer practitioners? The **Prime Minister** It is not a question of negotiation but of consultation, and of how this interim award had better be distributed and applied When we get the Royal Commission's report, I hope that we shall have a permanent solution of how the whole service will work in the future

Mrs **Jeger** When did the Royal Commission start work, and from whom has it so far taken evidence? The **Prime Minister** I am informed that the Royal Commission held its first meeting on March 13, the day after I announced its appointment, and that it has already held six meetings I understand that it has not yet received any formal evidence but has held preliminary and informal discussions with representatives of the consultants, the dental profession, the Bar, architects, chartered surveyors, accountants and different branches of the engineering profession Representatives of the consultants and the dentists made it clear at that stage that their presence did not commit their organisations to giving evidence

Mr **J E Ramsden** In view of the business like way in which the Commission is proceeding has my right hon Friend some hope that the doctors will, in these changed circumstances, modify their attitude towards the Commission? Will he make it quite clear, once and for all, that it will be within the competence of the Commission to have regard to the general relevance of the Spens report in its consideration of *the matter?* *The* **Prime Minister** *All these points of the* competence of the Commission were cleared in the exchange of letters which took place I think that the Spens report is generally regarded as wise and satisfactory On the question of the acceptance of the Commission, I can only repeat that I very much hope that everyone concerned will now turn his labours to the work of creating a satisfactory basis for the future remuneration *and future management of the health* service

The **Earl of Home** made the same statement in the House of Lords **Viscount Alexander of Hillsborough**, for the Opposition, welcomed the Government's retreat from their original *non possumus* attitude **Lord Rea** suggested that the Government were changing their point of view in a most favourable way, possibly using the Victorian example of Eric, or Little by Little, rather than agreeing on a final arrangement

QUESTION TIME

Health-service Contribution

Mr J A **Boyd Carpenter**, Minister of Pensions and National Insurance, in a written reply, stated On March 19 after taking the full advice available to me, I said that the existing health-service element in the National Insurance contribution was in that part of the contribution which is not allowable as a deduction for tax purposes I have now ascertained that this is not so It is, however, the intention that the contribution to be imposed on the insured person under forthcoming legislation should not be deductible for tax purposes, and I am authorised by the Chancellor of the Exchequer and the Minister of Health to say that the National Health Service Contributions Bill will deal in this way with the new health service contribution (which will subsume the National Health Service element in the present National Insurance contribution)

National Marriage Guidance Council

Mr E G **Fletcher** asked the Secretary of State for the Home Department what representations had been made to his department for an increased grant to the National Marriage Guidance Council—Mr R A **Butler** replied The National Marriage Guidance Council has expressed to me its disappointment at the amount of the grant of £10,000 proposed to be paid to it in the financial year 1957–58 In addition, since the Home Office estimates were published I have received 13 representations that the grant to the council should be increased Mr **Fletcher** Will the Home Secretary bear in mind that at present the taxpayer is spending about £1 million a year in subsidising divorce under the Legal Aid and Advice Act, 1949? Will he bear in mind also that the Royal Commission, while divided on the issue, was unanimous in recommending a marked extension in the work of education, premarital instruction, marriage guidance, and conciliation? Does he remember that the Royal Commission urged that every encouragement should be given to the existing agencies dealing with matrimonial conciliation?—Mr **Butler** I am sympathetic towards the aims of the council, and I should like to do my best for it The Royal Commission recommended a relatively modest increase in expenditure and the grant of £10,000 represented a 25% increase on the amount being paid at the time of the Royal Commission's recommendation. That does not mean that I regard it as entirely adequate, but it does mean that an *attempt has* been made

General Medical Services

The number of general practitioners under contract to provide unrestricted general medical services under the National Health Service in England and Wales on July 1 1956, was 19 082 The average number of visits by patients to doctors is in the region of 3 a year, and by doctors *to patients* in the region of 2

Group-practice Loans

So far the number of applications for loans from the Group Practice Loans Fund in England and Wales is 231 of which 107 have been granted The fund is now increasing by over £100,000 a year

In England Now

A Running Commentary by Peripatetic Correspondents

The doctor had seen Anne, aged three, on two successive evening visits to her dirty, crowded home She lay curled up, pale, mute and utterly miserable She refused all food He could find no clinical signs, and was puzzled and worried On the third day he asked for the help of the pædiatric department Could this sudden change from her normal cheerful behaviour mean an encephalitis or the onset of a tuberculous meningitis? The pædiatrician was puzzled too, and though, like the family doctor, he could find no clinical signs he thought the child looked ill enough to justify admission

In the ward, she remained curled up, pale, and apathetic Hospital investigations showed nothing significant Three days after admission we asked the psychiatrist to see her He was even more puzzled "The picture," he said, "is clear, quite typical, and immediately recognisable—this is the Child in Hospital The odd thing is that this is what you took her in for and she is now beginning to improve a little"

After further inquiry it all came out The other children, the mother said, had nagged and begged for a television set until finally she had given way and bought one—a 21 in model, she added This meant she had to go out to work to pay the instalments So Anne had been left for long hours sometimes quite alone

She is much better now, playing happily, and warm and friendly both to us and to the parents when they visit in the evening

The problem is one of disposal

* * *

Bang goes another link into the chain as we forge the destiny of our Nation No thermonuclear rumble, no supersonic crack, just another hallowed proverb pushed over the frontiers of human knowledge We have discovered how to make sows' ears into silk purses, to line them with gold, and wax fat on the profits *Meat Marketing* (March 23) reports that thanks to technology we now have a vibration colloid mill which makes more economical and more versatile sausages than ever before The manufacturers of this mighty maw claim, by grinding, emulsifying, and homogenising, to entice the last decimal return from rinds, sinews, cartilages, paunches, greaves, ears, and udders, and to offer as an end-product a mass paste which can be used to cheer our mash Real toad may yet line the hole

But surely the grinding emulsifying, and homogenising action of the mill does no more than reflect the changes in the world today? Changes which on one hand may strengthen our fibre and benefit mankind, or on the other wreck our vested interests and leave us even more crazily mixed-up kids If crusts from the bread and butter made our hair curl, rinds may make it stand on end The sinews of war have ever been strengthened by *armies* marching on their bellies The grinding of paunches may come perilously near to infringing the copyright of haggis, *but the walls of our own* stomachs shall *have ears to* hearken unto our borborygmi And as for udders, maybe emulsifying and homogenising will squeeze *out a* few more drops of the much-needed milk of human kindness The foie gras must look to its *pâte* *Only* time will tell whether our new breed of hot dogs will have a bark much worse than their bite The inside of our Honest John banger will *soon be a* greater mystery than ever

* * *

Dull surgeries make dull doctors Those G P s whose patients depress them should try the *hilarious* new game of surgery poker The poker-hands are made up from every five patients, in order of their appearance Coloured patients denote spades, red-heads, *blonde*, and dark-haired patients hearts, diamonds, and clubs, respectively Adults count as court-cards, *children* under 10 take the value of their age, and I play the convention which regards all chemists representatives as jokers and "*wild*

My best hand this winter has been a full house, kings high given by (in order of appearance) three adult males (all dark), one school-girl *(red-head)*, and one chemist's representative (bald) However, there are rumours that large families of West Indians are to settle in this area, so I have real hopes of a royal straight flush, which should earn me *The Lancet's* Bedpan of the Month

If anyone would like to sit in on the current game, openers are a pair of conjoined twins

* * *

"Odi profanum vulgus et arceo,' but there seems little one can do (if one must travel at that time) to lessen the crowds that push, fight, and squeeze themselves into underground trains between 5 and 6 P M One of my methods of making travelling more interesting is to study the faces of the people I meet, and from their clothes and accessories give a snap diagnosis of their job and the reason they are in that train But one can make mistakes I was strap-hanging last week in a crowded compartment when I noticed a book which attracted my attention It looked just like a *Synopsis of Surgical Anatomy* by a well-known author This must be a medical student, I thought (noticing his uncreased trousers and college scarf) Lucky young man, probably just rolling in for a quiet morning's dissecting, *or* a friendly lecture on the lymphatics Maybe—I thought as I noticed his age—he is an ex-Forces registrar taking a course for the primary fellowship And my wasted youth rose before me and with it a sorrow for never having taken my primary I might even have been a famous surgeon by now driving to town in my Rolls

I was shaken from my reverie by a sudden jerk, as we pulled up at a station, and some people got out, leaving me a seat next to my student I quickly sat down, determined to examine more closely the anatomical diagrams Yes, clearly "Head and Neck," always a difficult chapter The format of the book seemed a little unusual, however, the layout not quite right for a primary student Perhaps this was a real consultant (forced into a train by the petrol-ration) doing a little cramming before giving his midday tutorial His hair was nicely groomed, and had a most delicate perfume This must be a most fastidious surgeon Again the train pulled up and my student-doctor-surgeon, closed the book, and I followed close behind as we got out of the compartment, determined to see the title and author of his book *Anatomy for Hairdressing Students* loomed in gold letters before my eyes, and my dream vanished, bringing me back to England today, and the crowds trying to push through the ticket barrier But perhaps it is good that modern followers of Tod Slaughter take their studies so seriously—or is it?

* * *

How many of us really understand the physiology, psychology, or anatomy of the steed on whom we used to rely so much—our motor-car? But if what I hear is true, this is all to be remedied with the establishment of a College of Motor Anatomy

The first task of the college will be the clarification of instructional manuals of all popular models Such vague and misleading terms as "petrol pipe" and "jack" will be replaced by "ductus petrolificus" and "levator anguli Currus atque Rotarum" which will be so much clearer to medical men

Naturally the college will begin in a small way, but many of the teaching schools will soon enter into the spirit of the thing, found complete departments, and add a compulsory month or so to medical training Study will be broad and scientific, like all medical training Students will learn, for instance, the reasons for the extinction of the 9 H P Boggle Box Egg in 1932 A degree, bachelor of transport anatomy, will be conferred, with the abbreviation B TR A to distinguish it from the popular B T A, which, of course, stands for "Been to America"

Have the 'fall outs' assessed to a decimal,
Yet my nephew and niece
Have got five legs apiece,
And their intellect's infinitesimal

Letters to the Editor

SENIOR REGISTRARS AND CONSULTANT APPOINTMENTS

SIR,—The figures relating to consultants and other specialists staff in hospital (April 13, p 785) will be read by those training or intending to train as specialists not only (as you suggest) with interest, but also with dismay and despondency

For example, the tables show that, whereas in 1957 only 11 general physicians will have reached the age of 65, there are as many as 27 senior medical registrars in their fourth year and 68 "others," which include those holding "transitional" posts Even this high figure of 95 potential candidates for consultant appointments may be an underestimate since university lecturers and research-workers are not included in this group

On the basis of the previous report, Mr Morgan[1] has shown that it would take some eight to eleven years for all senior registrars in the major specialties to be absorbed by retirement vacancies Last October Dr McGregor[2] reported that only a third of the senior registrars in the South East Metropolitan Region who completed their training during the period 1952–56 had so far become consultants, and that this status was achieved from twelve to sixteen years after qualification

It is well known that there may be as many as 40 or 50 men of 35–40 years of age still applying for each consultant vacancy Many of these men have had a few years of war service and the majority have growing families to support, with children at school Periodic moves around the country may involve separation from one's family for many months on end The recent increase of 10% in salary, welcome though it is in helping to relieve financial hardship, cannot be accepted as the only solution to the serious situation which has arisen through lack of security of tenure and poor prospects of promotion

Recent correspondence in the journals and national press has shown that the plight of senior registrars is certainly fully appreciated by our consultant colleagues Mr Harold Dodd[3] offered a constructive contribution when he wrote "I think that it is a national need that the office of assistant physician and surgeon be reintroduced, and that our registrars be given status and reasonable security after their arduous and expensive training"

Sir, can the ever present, yet still urgent, plight of senior registrars be solved? It is recognised that senior registrars may already be doing consultant work for many months in the year In fact, in non teaching hospitals one may deputise for as many as four consultants and therefore be in complete clinical charge of beds and outpatient clinics for at least six months in the year

I would suggest that one possible solution would be to discontinue the posts of senior registrars in non teaching hospitals as they become vacant and appoint assistant physicians and surgeons to the hospital staff in their stead It is important that such appointments should not be regarded as in any way being a sub consultant grade On the contrary, those selected should be given the status of junior consultant with every opportunity for promotion at a later date

These junior consultants would continue to act as deputy to their senior colleagues but, as has been stressed, the appointment should also entail "a few beds, a small outpatient session, and, most important of all, the right to private practice"[4] However, if in certain circumstances this right to private practice is not immediately envisaged, my personal view is that such appointments could be held initially on a whole time basis In any case, it seems unlikely that the cost to the country of this transition would be much in excess of that already entailed under the present day senior-registrar scheme

---

[1] Morgan, T H *Brit med J* 1956 ii, suppl p 204
[2] McGregor, H G *Ibid* p 159
[3] Dodd H *Ibid*, p 204
[4] Sewell, W *Lancet*, 1955, ii, 873

Critical analysis of this plan for resolving the senior-registrar problem may well reveal certain flaws and deficiencies, and it may require modification Nevertheless, by limiting new senior-registrar appointments to teaching hospitals and postgraduate centres, a reasonable ratio of senior-registrar to consultant establishment will be maintained Senior house officers and registrars will no longer be fearful of their further prospects, and applications for these posts, which are now far below the vacancies available, will surely increase

Dr Horace Joules[5] has written "as the years pass many senior registrars, excellently trained, are approaching middle age and abandoning hope of obtaining full recognition and employment" Is our long period of training and responsibility to be wasted? All we ask is that our services, which we willingly give, may receive recognition and that some reasonable hope for the immediate future be offered

Bristol   A G FREEMAN

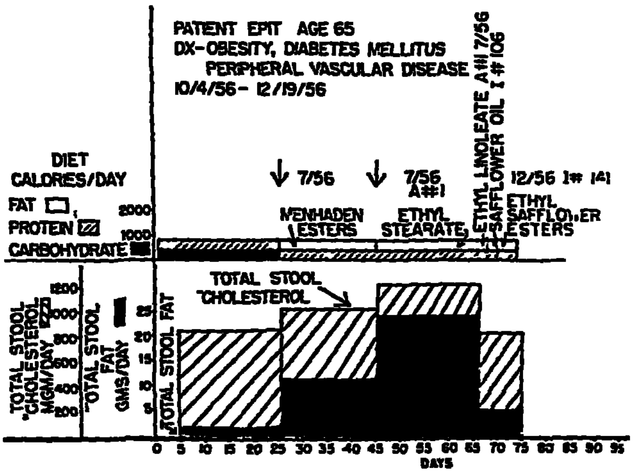
FATS AND DISEASE

SIR,—The paper by Keys, Anderson, and Grande entitled "'Essential' fatty acids, degree of unsaturation, and effect of corn (maize) oil on the serum-cholesterol level in man" in your issue of Jan 12 calls for comment because we believe the authors have not drawn the correct conclusions from their experiments

The authors believe that in general serum cholesterol levels are directly related to the total consumption of fat rather than inversely related to the consumption of essential fatty acids, and that the effect of vegetable oils in lowering serum cholesterol is not the result of the essential fatty acids (particularly linoleic acid) in them They have fed corn oil, sunflower-seed oil, sardine oil, and butter fat to schizophrenics for two weeks The serum total-cholesterol rose after the change from corn oil to sunflower seed oil, and fell after the reverse change, the average difference being 9 3 mg per 100 ml, the values were higher after sardine oil than after corn oil, the average difference being 20 2

There are several objections to the conclusions regarding essential fatty acids that are reached by the authors

1 The actual qualitative and quantitative fatty-acid composition of the oils was completely unknown, and since (as we show below) corn oil appears to produce different effects upon serum-cholesterol in Keys's laboratory at different times, this is crucially important The authors give the iodine numbers of the oils but they take values for linoleic acid from the literature Sunflower-seed oil, with an iodine number of 131, was assumed to have a linoleic-acid content of 61%, "typical variations" given by Hilditch[6] are from 19% to 72% for linoleic and from 14% to 71% for oleic acids, which together are responsible for the iodine number Corn oil, with an iodine number of 120, was assumed to have a linoleic-acid content of 45%, recent commercial samples of U S corn oil had extremes of linoleic acid from 16% to 68% and of oleic from 20% to 76%, a U S corn oil analysed by Lofland et al[7] had an iodine number of 122 and linoleic acid content of 51%, while one analysed by Sniegowski and Baldwin[8] had an iodine number of 121 and linoleic-acid content of 52% It is not apparent to us why Keys and his colleagues have selected a figure as low as 45% Though it is probable that the difference of 11 in the iodine number of the two vegetable oils represents a difference in linoleic-acid content, this is not certain Further, nothing is known of the steric configuration of the linoleic acid in these oils



Absorption of ethyl esters of menhaden oil ethyl stearate and ethyl esters of safflower oil The formula diet used was quantitatively constant. Protein vitamins, and minerals remained unchanged throughout the study

The position regarding the sardine oil is still more unsatisfactory Information is neither given nor available about the content of essential fatty acids in this, and no information is given about any processing or deodorising it may have received Fish oils vary in their growth-promoting activity upon rats deficient in essential fatty acids one of us (H M S) found that samples of herring oil (*Clupea harengus*) and of pilchard oil (*Sardina ocellata*) were each very active in promoting growth when fresh but not when old, whereas samples of Japanese sardine oil (*Clupanodon melanosti*) and of cod-liver oil (Ministry of Food) were without growth-promoting activity If, as is probable, Keys and his colleagues used pilchard oil (probably from *Sardinops caerulea*), the age and treatment of this are important and the iodine number does not give the required information about fatty-acid composition Bronte-Stewart et al[9] found that South African pilchard oil (presumably from *S ocellata*) in fact lowered serum-cholesterol in man It is fantastic to make claims about the relative potency of different oils in essential fatty acids on the basis of iodine numbers

2 The efficiency of absorption of the oils used by Keys and his colleagues was apparently unknown That this may be a factor of real importance is shown in the accompanying figure, representative of studies recently carried out by Michaels and his associates[10] It is obvious from this that absorption of the ethyl esters of menhaden oil (a fish-oil preparation with an iodine number of 139) was extremely poor The same statement applies to esters of palmitic and stearic acid (iodine number=1) whereas the ethyl esters of safflower oil (iodine number=141) are without exception extremely well absorbed

3 In our laboratories, the changes in serum-cholesterol during the two-week periods on corn oil, sunflower-seed oil, and sardine oil—namely, mean changes of 9 3 and 20 2 mg per 100 ml—would be regarded as being within the range of spontaneous fluctuation unless very frequent estimations were made

4 The behaviour of corn oil in Keys's laboratory varies with the passage of time In 1950 he and his colleagues found that corn oil produced a rapid rise in serum-cholesterol in a patient with idiopathic hypercholesterolæmia who had been on a fat-free diet, and Keys concluded[11] that "there is not the slightest evidence for a difference between animal and vegetable fat in this regard [effect of fat intake on serum-cholesterol]" In experiments on 21 male schizophrenics reported in 1952, Keys found[12] that vegetable fat ("mainly corn or maize

[11] Keys A *Circulation* 1952, 5, 115

[12] Keys A *Voeding* 1952, 13 539

oil, "as such or hydrogenated to form a vegetable margarine") raised serum-cholesterol the average rise in passing from a diet containing 11 g of vegetable fat to one containing 110 g was 64 mg per 100 ml, and a fall of 61 mg was obtained when the fat in the diet came from two eggs, Keys concluded "that vegetable as well as animal fats have this effect" of raising serum-cholesterol That the serum-cholesterol of the schizophrenics over the past four years had shown "a direct response to change in fat calories, with no indication of an effect of the kind of fat in the diet" was reiterated in 1954[13] At this time

> "most of our demonstrations of the effects of fat intake have been made with corn oil or cottonseed oil or both Recently, however, we have carried out an elaborately controlled experiment on 24 men in which olive oil and cottonseed oil were compared These fats were chosen because, among common food fats of vegetable origin, they have the greatest chemical dissimilarity Besides the use of control (before and after) periods, each subject was studied on both types of fat, and the effect of sequence was also controlled No difference between the effects of olive oil and of cottonseed oil on serum cholesterol concentration could be found"

An average content of linoleic acid in olive oil would be about 6% and of cottonseed oil about 49%, and if indeed these two oils raise serum cholesterol equally the details of this experiment should be published

The similarity in cholesterogenic action of these two oils was repeated, again without details, in September, 1955[14] A year later (October, 1956) Keys had come near to the importance of essential fatty acids which we have been stressing when he concluded[15] that "Hard fats are more [cholesterogenic] than fluid oils The 'essential' fatty acids, linoleic and arachidonic, probably have a different effect than such fatty acids as palmitic and stearic" In a recent paper,[16] Keys is reported to have stated that "coconut oil is outstanding as having the same kind of effect as do meat and dairy fats Some of the oils, however, such as corn oil, do not promote cholesterol increase in the blood As a matter of fact, if taken in large quantities, they depress the cholesterol blood level The level of cholesterol in the blood with a cottonseed-oil diet is about the same as with a fish-oil diet" In his letter of April 13 (p 787) he now recognises that saturated, mono-ethenoid, and poly-ethenoid fatty acids differ in their effect on the blood-cholesterol

Vegetable oils are not immutable nor is man infallible The cause of Keys's altered views might be a change in the composition of the oils he has used, and this possibility, which is not the only one, emphasises again the need for knowledge of this composition if conclusions are to be drawn from slightly different responses to different oils

A great deal more work is required to clarify the effect of feeding different oils upon serum cholesterol The paper of Keys and his associates does little to provide such clarification It is known that the feeding of a synthetic triglyceride containing unsaturated fatty acid is associated with a major decrease in serum cholesterol as compared with the level existing during the ingestion of an equal amount of vegetable fat essentially devoid of unsaturated fatty acid[17] Unpublished data from the same laboratory demonstrate similar effects with purified ethyl linoleate[18] We believe that the essential fatty acid content of dietary fat is the primary factor responsible for the lowering of serum cholesterol, but there are secondary factors as already discussed by one of us in your columns,[19] such as the content of tocopherols and of steric isomers of the fatty acids However, data now being prepared for publication by one of us (L W K) indicate that under appropriately controlled conditions, fresh readily absorbable vegetable oils have serum cholesterol lowering effects that are in fact approximately proportional to their iodine numbers

Oakland, California — L W KINSELL
Oxford — H M SINCLAIR

SIR,—*It should not be too difficult* to ascertain which group of people in this country consume the largest quantities of animal fats—personally I suspect farmers (not farm labourers)—and compare them with a similar group of men (unemployed) for the incidence of coronary thrombosis If the two groups chosen smoked the same number of cigarettes per day, the comparison might be even more helpful Meanwhile, many doctors have cut down their intake of animal fats in the hope of avoiding the disabling consequences of what has been regarded as their own specific vocational hazard Sir John McNee[1] maintains that only in the rabbit has atheroma been proved to be associated with a high intake of cholesterol Will some kind medical statistician please assure me that I can return to my former (modest) ration of eggs and butter?

Hull — L I HARDY

LETTERS FROM HOSPITAL

SIR,—As a general practitioner I am very grateful for the help I receive from consultants, but *this help is* not infrequently marred by the delay in the arrival of their letters, whether they refer to outpatients or inpatients I know that consultants are hard worked, but so are G P s, and yet no patient of ours is accepted as an outpatient without our letter accompanying him Moreover, delay does not diminish the amount of work that has to be done eventually

But there is one way in which consultants could very often save time and labour In the reports I receive half or three quarters is often devoted to repeating the patient's past history and present complaints These are *things* which the G P knows at least as well as the consultant and which were set out in the G P's letter Though the consultant will, of course, want to elicit from the patient his own story, he need not report *it* back to the G P *Shall* we add "*unless he learns something* which he thinks may not have been known before"?

One consultant I know hands his reports (diagnosis and suggested treatment) straight away to the patient to take back to his own doctor This seems to me a very satisfactory arrangement which I would like to recommend

Croydon, Surrey — W J PINCH

POLYNEURITIC REACTION TO AUREOMYCIN

SIR,—I have lately observed a polyneuritic reaction to aureomycin (chlortetracycline) As far as I am aware, such a reaction to aureomycin is rare

A woman of 36 years had pneumonia during the winter of 1948–49 while living under difficult war conditions She has since suffered recurrent bronchitic infections, which seem to be localised in the right lower *lobe* Various chest specialists suspected bronchiectasis, but 2 bronchograms did not show clearly localised lesions The diagnosis has therefore remained uncertain

The bronchitic exacerbations used to be much improved after treatment with penicillin, which she has received repeatedly In September, 1956, the patient *had* a bad anaphylactic shock after an injection of a mixture of benzathine penicillin and procaine penicillin *There* followed a period of disturbed sleep, disturbances of vision, and some feeling of tingling in hands and feet On March 10, 1957, after receiving aureomycin *1250* mg daily for 4 days for an exacerbation of the bronchitis, she had a polyneuritic reaction, glossitis, and disturbances of vision There were paræsthesiæ and hyperæsthesiæ of hands and feet, tenderness of the muscles of the left calf, and some impairment of the sense of light touch and of hot and cold differentiation Vibration sense was normal, as was stereognosis Reflexes were normal All the disturbances in hands and feet, in the typical stocking and glove distribution, ended proximally without sharp limits, and gave way to normal sensation She had difficulty in accommodation. There was no impairment of the function of the external ocular muscles

A YUVAL

HOSPITAL MEDICAL RECORDS

SIR,—Dr Skelton (March 30) and Dr Brocklebank (April 6) both view the problem of preserving medical records and X-ray films from the standpoint of the space needed for their storage

Staffing difficulties must also be considered The retention of medical records is not merely a matter of stuffing them into filing cabinets, or stacking them on shelves To be of value to the clinician or research-worker, records must be suitably indexed and classified (under medical direction), and properly filed by trained clerks An adequate medical records service can be extremely expensive in staff

It is not always appreciated (even by doctors) that the increased number of administrative and clerical staff seen in the hospitals since 1948 is due in large measure to the demands of the vastly improved medical-records service now generally offered Further improvement in this service must result in the employment of yet more clerks

L W HUNT
Hospital Secretary

Aberystwyth General Hospital

STAPHYLOCOCCAL BRONCHOPNEUMONIA

SIR,—The interesting article by Dr Gresham and Dr Gleeson-White (March 30) is timely and of great importance This problem is not confined to one hospital Although it is widespread, some hospitals are much more aware of the problem than others We have been studying the general problem of hospital staphylococcal infections and recently have been concentrating on the patients with pneumonia

An analysis of the first 25 cases of staphylococcal pneumonia obtained from the clinical records of the University Hospitals for the past five years shows that 20 of them were fatal and that a majority occurred in debilitated patients 19 of them were over 50 years of age and there was a slight lessening of incidence in the spring and early summer In 12 cases the disease was not suspected before death Fever, cough, dyspnœa, and mental confusion were the commonest signs A third complained of pleural pain Sputum production was not prominent The X-rays of 19 patients showed that pulmonary infiltration was the only constant finding There were only 4 cases with abscesses and in 2 the hilar glands were enlarged At necropsy the predominant finding in 20 examinations was a diffuse bronchopneumonia, which in 5 instances was described as necrotic Hæmorrhage in the lung was mentioned only once, but it is of interest that 3 other cases had bloody sputum and 2 others clinical purpura These cases, of course, are only indicators of an underlying problem We cannot include patients with undiagnosed antibiotic cured pneumonia and those who died, undiagnosed, without necropsy

Other studies by this group have shown that in the 1935–41 period there were about 20–30 cases of staphylococcal septicæmia seen yearly, whereas after this until 1953 only 5–10 were seen Since then a gradual climb in numbers is evident and in 1955 we saw 27 patients with staphylococcal septicæmia

We made some studies of the prevalence of staphylococcal infections in hospitalised patients similar to those made by Finland and Jones [1] In a group of 634 patients 70 (11%) had proved staphylococcal infection compared with 15% of the patients in the Boston study We had 3% of serious infections compared with 2 6% in their series 56% of our infections appear to have been acquired in hospital (62% in theirs) In addition a study of last year's 484 necropsies, through the kind permission of Dr Emory D Warner, shows that hæmolytic *Staphylococcus aureus* was the prime cause of death in 3 7% of cases and may have been a secondary cause in 12 5% of necropsies

A continuing study of staphylococcal infection is being carried out by a more intensive survey of the wards for incidence and ecology of staphylococcal disease In this study, one of us, a member of the nursing staff, is making observations on nursing and medical procedures and the relationship of these activities to cross-infection

CÆSAREAN SECTION

SIR,—I think the conclusions in your leading article on cæsarean section (April 6) are rather misleading I have discussed the problem of the indications for cæsarean section at length,[2] and since my conclusions would seem to be at variance with your own I would like to make the following comments

You say that half the fœtal deaths in deliveries by cæsarean section are attributable to the risks inherent in the operation itself This is certainly not my experience, in fact, I cannot remember a single case in which this was clearly so In some cases where the baby died, earlier resort to cæsarean section might have prevented the death Your recommendation that we should hesitate before deciding to operate solely in the interests of the child therefore needs amplification

Between the periods 1938–47 and 1953–56 the perinatal mortality-rates in booked hospital primigravidæ in Aberdeen fell by more than a third, and the decrease was greatest in the older women, in those of 30 years or more it fell by 75%

Perinatal mortality per 1000 births

Age-group	*15–19*	*20–24*	*25–29*	*30–34*	*35 –*	*All ages*
1938–47	36	35	57	76	101	45
1953–56	40	26	28	17	25	28

The cæsarean-section rate in booked primigravidæ was 1 3% in 1938–47 and 4% in 1953–56 The increase was least in younger and most in older primigravidæ, in those of 35 years or more the cæsarean-section rate is now about 30%

After about 25 years of age, primigravidæ show a progressive deterioration in uterine function which shows itself in a tendency to intra-uterine death of the fœtus and to prolonged labour due to disordered uterine action These dangers are increased if labour does not take place by the 40th week, and may be further increased if pre eclampsia is present The avoidance of protracted pregnancy by induction of labour and of protracted labour by the more liberal use of cæsarean section seems to have been successful in preventing many such deaths without increasing the risks to the mother The overall maternal mortality of 0 99% following cæsarean section, reported by Marshall and Cox [3] for the years 1943–47, no longer applies, since in many maternity hospitals in Britain it is now by no means unusual to perform several hundred consecutive cæsarean sections without a death

---

1 *Ann N Y Acad Sci* 1956, 65 191
2 Baird D *Brit med J* 1955 ii 1159
3 Marshall C M, Cox L W Transactions of the 12th British Congress of Obstetrics and Gynæcology, 1949 p 30

Fortunately, cæsarean section is seldom indicated in young women except for disproportion, since it is prejudicial to further childbearing But few primigravidæ over 30 years of age have a second child, so it is particularly important to do everything within reason to ensure that the first baby is born alive My experience is that the chances of a satisfactory outcome can be greatly improved by resort to cæsarean section in cases where there exist one or more potential hazards to fœtal life There seem to be no disadvantages in such a policy except possibly in relation to future pregnancies

Midwifery Department
University of Aberdeen DUGALD BAIRD

SIR,—Practising obstetricians will agree with Mr Higgins (April 20) that the picture painted in your leading article of April 6 is an unjustifiably bleak one of delivery by caesarean section today, but this state of affairs is inevitable as long as figures of mortality surrounding the operation are taken as a yardstick Thirty years ago the mortality connected with the operation was large enough for the statistics to be helpful, but different types of statistics are required today

Mr Higgins quotes his own excellent figures since 1943 of 1114 sections with 2 maternal deaths, in only 1 of which could the operation be considered a contributing factor The real question is, however, what of the 1112 surviving mothers and their babies? Would they have been better dealt with by other means? But it goes further than that What of the other mothers in Mr Higgins's catchment area during these years? Are there any mothers and babies (still and live born) whose situation would have been better today if cæsarean section had been used as a means of delivery?

These are the real questions at issue, and that they are not answered by the mortality figures is obvious It is for this reason that the obstetric art can never be replaced adequately by obstetric technique

In this supersonic age, I find contemplation of this encouraging

South Shields TERENCE G ROBINSON

THE Rh BLOOD-GROUPS

SIR,—Dr Wiener (April 13) suggests that a gene-dosage effect could "readily explain" our findings,[1] and that our use of the CDE notation has led us to make the "blunder" of describing as "Strong D," bloods which are merely homozygous DD But is this really so, and if so, how does Dr Wiener explain these points?

(1) Only 5 examples of Strong D were found amongst 653 random samples tested 227 homozygous DD samples would be expected in this number

(2) Our paper shows tests on 8 CDe/CDe, 3 CDe/cDE and 1 CDe/CDE samples (probable genotypes) These came from unselected individuals, and none gave the reactions of Strong D Are we to assume that the genotypes of all these were really heterozygous Dd? In the English population, 4 5% of individuals of probable genotype CDe/CDe are actually heterozygous Dd Similarly, 11 0% of those of probable genotype CDe/cDE and 2 3% of those of probable genotype CDe/CDE are heterozygous Dd, so that the probability that all the twelve samples mentioned above were Dd is only about 10^{-15} [2]

(3) There are two sisters in our family Tr who must be of identical Rh genotype, yet the D antigen of one shows twice the reactivity of the other

The Rh genotype does appear to have some influence on the reactivity of the D antigen, as, in fact, we pointed out in our paper, but we fail to see, in view of these considerations, how it can be the only factor involved

Furthermore, it seems to us that our observations remain the same no matter what nomenclature they are expressed in, so we do not think the CDE notation ca be blamed for whatever defects there may be in ou paper Our experiments are equally valid, and could b equally well expressed, in either notation

National Blood Transfusion Service,
Manchester 1
P H RENTON
JEANNE A HANCOCK

CHRONIC BRONCHITIS AND SMOKING

SIR,—I disagree with the view expressed by Dr Harl Williams (April 13) that smoking is "an enjoyab habit" I do not think smoking is a habit It is a dru addiction, a disease There is a habit factor— in opium and hashish smoking—but it is utterl unimportant

Nor do I think smoking is enjoyable The pleasure taking drugs is psychopathic—as are the pleasures of th sadists and masochists After-depression is inevitabl and outweighs the immediate pleasure Like D Anderson (March 30), I think it seriously wrong tha a NAPT leaflet should describe smoking as "a ver pleasant social habit"

Wallasey, Cheshire LENNOX JOHNSTON

INSULIN TREATMENT OF SCHIZOPHRENIA

SIR,—The controlled study of Dr Ackner and hi colleagues (March 23) appears to me to be one of the mos valuable psychiatric researches in recent years If the conclusions are borne out by the further results which the promise, they will have conferred an immense benefi on both patients and psychiatrists

Much has been written about the danger of personality deterioration following prefrontal leucotomy A good deal has been said about the possibility of cerebral damage as a result of electroconvulsion therapy (E C T) As far as I can ascertain, very little has been mentioned about the very real danger of insulin-coma therapy to life itself

During the three years that I was directly responsible for an insulin clinic, I never in fact lost a patient, but on three occasions I came very close indeed to doing so In the first case the patient developed status epilepticus which was controlled only by deep anæsthesia He recovered after about 24 hours, but I was at his bedside for practically all of that time The second case was one of "irreversible" coma which required a similar period of anxious and close attention The third was a healthy young hebephrenic who developed peripheral circulatory collapse while recovering from a normal half hour coma She was saved only by very prompt measures. There were, of course, numerous experiences of a less dramatic type I have personal knowledge of two deaths directly attributable to insulin coma therapy, at a time when I was not responsible for the insulin clinic concerned

I have for years had a very strong impression that equally good results could be obtained by less hazardous and anxiety-provoking procedures (for example, E C T) I am sure that this view is shared by many other psychiatrists

It appears to me that if insulin coma can be proved, by scientifically controlled research, to be no more efficacious than safer methods of treatment, a positive advance in psychiatry will have been made

For this reason the remarkable work of Dr Ackner and his colleagues seems to me to be of the utmost importance

Royal Earlswood Institution
Redhill, Surrey G J F FRYER

SIR,—Without taking sides in this controversy, it may perhaps be worth observing that, as so often occurs in learned scientific discussions, what finally separates the two chief disputants appears to be not so much a scientific as a philosophic difference not so much a collision of facts as a collision of emotional convictions Once this is grasped, the rest of us may safely enjoy these ingenious polemics without falling into the dangerous error of

---

1 Renton P H Hancock J A *Brit J Hæmat* 1956, 2, 295
2 Calculated from Race, R R Sanger, R Blood Groups in Man Oxford 1954

mistaking them for unbiased testimonies to scientific truth

We may thus read Dr Ackner's paper with such reservations as may be engendered by an awareness of the kindly vitalistic philosophy which colours his conclusions Similarly, a recognition of the fanatically mechanistic outlook of Dr William Sargant will enable us all to appreciate in his reply (April 13) the curious spectacle of a man becoming emotional about the unimportance of emotional factors—an impassioned robot, as it were, fighting for his dear mechanical life

London W 1 ALAN MCGLASHAN

SIR,—As indicated by Dr Ackner and his colleagues, their finding that insulin treatment as such has no great advantage over other therapies has been reported frequently, sometimes with the imitation regime adopted by them

In 1938 Dr Gillman and I[1] found that during the first year after admission of 151 schizophrenics diagnosed by the same observers in the same hospital, 66 1% of 59 who had had 50 or more insulin comas (unless cure was established with a smaller number) went home in an average of 4 3 months, 58 3% of 12 who had had prolonged sleep went home in 5 8 months, and 65% of 80 went home in 7 2 months after no other treatment than ordinary nursing and the psychotherapy of friendly interest Insulin saved time, to which might be added a better doctor patient relationship and the value of a group setting The superiority of the proportion of cures was negligible, but, in general, the bigger the sample, the more certainly does the slight superiority of insulin treatment become significant, and I agree with Dr Sargant that it still has a special place in treatment

I cannot agree, however, with much of his argument —for instance, the phrase "properly selected patients" Are there any impressive follow-ups which show that an appreciable number of schizophrenics treated in mental hospitals, who form the bulk of those about whom statistics are available, were not suffering from schizophrenia at all? (There are such follow-ups which show that many hysterics, &c, were in fact schizophrenics) If not, then "properly selected" really means "thought to have a better prognosis" Again, the "number of comas" contains a fallacy obvious to those with long experience, whether medical or nursing, often after 20 comas it is clear that 120 comas will not produce improvement so that the "more than 40 comas" group tends to include more hopeful cases

Dr Sargant writes " all we used to have at our disposal were the many and varied types of psychotherapy which all proved so very disappointing, when used alone, both inside and outside mental hospitals" I do not know how many schizophrenics Dr Sargant has treated by consistent and time consuming psychotherapy only, but in my experience this is easily the best form of treatment yet available provided that an "acute" episode does not make its continuation temporarily impossible When the early symptoms (difficulty in thinking reduction in the ability to plan, difficulty in separating past thoughts from past events, reduced ability to recognise absurdity and failing insight,[2] to which I would now add mental slowness[3]) develop insidiously, a psychotherapist is at present the most appropriate physician and this despite the fact that such early schizophrenics are usually thought to be psychoneurotic only—a tribute at least to the personal approach of the psychotherapist It is a great pity that more psychiatric time is not available then and for supportive psychotherapy for chronic cases (I think it possible that many of the best results of psychotherapists are achieved with mild undiagnosed schizophrenics)

Further, I agree with Dr Sargant that highly trained near-permanent nursing staff are essential for adequate insulin therapy and that the physician should be able to give E C T. as indicated, and I also agree about the extra value of very deep comas which, I think, should aim at a reversible "irreversible" state, for it is the brain-damaged schizophrenics who do best, as if, at any rate, they now had less but only healthy brain tissue available[4] It is these who provide "the little extra" of insulin treatment I cannot say whether they bear any relation to the group indicated by Dr Batt and his colleagues (April 13)

St Ann s Hospital
Canford Cliffs Dorset D N PARFITT

SIR,—Dr Sargant, after casting doubt on the experience of our medical and nursing staff, says that our " excellent results reported despite these drawbacks suggest what can be achieved with insulin-coma . . by highly trained and experienced therapists in properly selected patients " The fact is that no better validated results have been reported, even though criteria far less strict than ours have been used He asks whether many experienced therapists really believe that insulin is the specific agent of recovery in insulin coma treatment If this has not been their belief we wonder why so much research has been undertaken into the physiological effects of insulin coma, usually with inconclusive results He suggests that we were attempting to demonstrate the psychotherapeutic aspects of the insulin regime and asks why sterile water was not used Our project was designed as a scientific inquiry into the value of insulin-coma treatment and for this purpose we attempted to control as far as possible one variable—namely, insulin It was thus necessary for the patients to go into coma We pointed out that the value of the coma treatment could not be ignored and indicated its possible effect on building up new relationships But we did not conclude that schizophrenia should be treated by psychotherapy alone or that physical treatments should be abandoned We do not deny that coma by itself may have some beneficial physiological effects, though this remains to be demonstrated But if Dr Sargant believes this to be true he must take note of the fact that barbiturate coma is a far less dangerous and expensive treatment than insulin coma and that our results show the outcome to be equally good

Dr Batt and his colleagues in fact assume that insulin coma has a specific physiological effect on properly selected cases They question our method of selecting cases on the basis of clinical criteria, but we can only answer that this is the method which has been used, for over twenty years, by those who have made claims for the value of insulin therapy If selection for treatment could be based on properly validated endocrinological criteria, this would be an advance welcomed by all But in the published work quoted by Dr Batt and his colleagues no figures are given to support their claims and many different patterns of 17 ketosteroid excretion rates appeared compatible with improvement occurring both spontaneously and concomitantly with treatment

Dr Edwards (April 6) has fallen into the old error of assessing the value of a treatment by means of discharge rates Our figures showed similar results for the insulin and control groups when those who were "recovered" or "independent" were considered Social factors and discharge policy may often determine whether a patient who is still unrecovered and "dependent" can return home or must remain in hospital Discharged and not discharged cannot, therefore, be regarded as equivalent to success or failure respectively His statistical criticisms are unacceptable for they fail to take into account previous claims for insulin treatment If the control treatment can produce results as good as those previously achieved with insulin, then naturally spectacular results for insulin would be required for it to be claimed as a significantly better treatment Dr Edwards claims that "it seems very questionable whether such a trial can reveal therapeutic advantages with the precision of the casually acquired beliefs of experienced observers" Casually acquired beliefs are never precise and there is at the moment a marked divergence of opinion amongst experienced observers as to the value of insulin treatment

DAY HOSPITALS

SIR,—Dr Arthur Harris's article of April 6, on Day Hospitals and Night Hospitals in Psychiatry, contains one or two inaccuracies

First, although my first paper on the Day Hospital appeared in 1951, the unit was planned and organised in 1944–45 and was put into operation in 1945–46 It is true that Cameron started his day hospital in Montreal at the same time, but these two independent experiments were conducted simultaneously and without knowledge of each other's existence for two or three years

Secondly, it is misleading to speak of day hospitals when we mean day units There are three distinct forms of day unit which have so far emerged (1) the day ward, which is a ward attached to, and part of, a mental hospital, (2) the day department, which is attached to and part of a teaching or general hospital, and (3) the day hospital, which is an independent unit comprising all the facilities for treatment available in modern psychiatry and is therefore replacing the modern mental hospital

Thirdly, apart from other differences, the cost per head in these various day units also differs The full cost for the treatment of 914 patients last year in the Marlborough Day Hospital, which comes into the third category of day unit, was less than £25,000

HIATUS HERNIA

SIR,—I agree with much of what was said in Dr Phear's article of April 6 I would like, however, to take issue with him over several points

Any surgeon who is working in œsophageal disorders realises that there is a great place for medical treatment For example, in this unit in the past two years, while 70 sliding hiatus hernias have been operated on, 32 have been treated medically with success, and while 16 paraœsophageal and rolling hiatus hernias have been operated on, 5 have been treated medically As regards those cases with an incompetent cardia, 6 have been operated on and 7 treated medically

I could not disagree more with his remark that there is a high recurrence rate after surgery If an Allison repair is carried out, which after all is a physiological and anatomical operation, then the recurrence rate is extremely low—i e, 2% There is no doubt that those cases presenting with gastro-œsophageal reflux which is persistent, and who have to earn their living in occupations which demand bending and stooping, should surely have the cardia rendered competent It is almost fatuous to tell them to follow a medical régime, particularly if their life expectation is another 30 to 40 years

I am sure that Dr Phear did not really mean it when he said that surgery should be considered when the hernia undergoes strangulation or torsion Gastric strangulation is a lethal condition and demands urgent treatment, and certainly if a patient with a paraœsophageal pouch has any symptoms of obstruction, surgery should be undertaken forthwith There is a mortality rate for medical treatment of a paraœsophageal hernia

Southampton General Hospital

E F CHIN

INFUSION NEEDLES

SIR,—I was interested to read of Dr Furniss's difficulties with the needle provided with giving sets (April 6, p 739)

Some years ago when I was a resident I obtained an intravenous trocar and cannula, of which I believe there are several types on the market, and found this not only more satisfactory for getting into veins, but less likely to result in thrombosis when in situ The cannula was fitted with a 'Record' mount so that the rubber tubing of the standard giving set could be easily attached to it If the cannula should become blocked it was possible to free the block by inserting the trocar

With this instrument I rarely found it necessary to cut down, even on the patient with the most difficult veins

London, W 1

N A THORNE

MOSQUITOES AND MYXOMATOSIS

SIR,—In your annotation of Feb 2 you mention that the aedes mosquito is not attracted by healthy domestic rabbits, which remain uninfected though exposed to the bites of mosquitoes carrying the virus of myxomatosis

It is interesting to note that Hagedoorn[1] argues that the domestic rabbit is possibly a leporoid, a hybrid of the wild rabbit and the hare, and though this is not universally accepted it may offer an explanation for the difficulty in passing on the infection One would like to know whether the experiment has been tried with caged wild rabbits

Brightwater,
Nelson, N Z

R L HAVILAND MINCHIN

SUBUNGUAL HÆMATOMA

SIR,—The methods outlined in your annotation of April 13 for treatment of this common injury suggest the use of bayonet or red hot poker to burst a balloon I have abandoned their use, over the past year or two in favour of a technique which is quick, safe, and usually painless, and I have so dealt with several dozen lesions

The subungual hæmatoma almost always has a margin which approaches the surface very nearly, usually at the distal edge of the nail, the tip of the finger is swabbed with antiseptic and any type of sterile sharp point is then introduced under the nail, penetrating only a hair's breadth of epidermis to provide immediate decompression and free drainage

This method needs no anæsthetic and has not produced a single case of sepsis, whereas infection is not uncommon after the drilling procedure owing to the smallness of the drainage hole and subsequent intermittent reflux of serum through it and its not infrequent blockage

Southport General Infirmary,
Southport

P J W ROWELL

SIR,—May I point out that the method you attribute to Ashford (using a red-hot needle or wire to penetrate the nail) is also quite painless and that no local anæsthetic is necessary ? I do not have access to Ashford's paper but I saw the method described elsewhere over eight years ago and have used it repeatedly ever since, a medium-size safety pin is about right, and I sometimes make two holes without any protest

GOVERNMENT AND PROFESSION

SIR,—I wish to comment on your two editorials (March 30 and April 13) It is obvious that somewhere we have parted company, in my opinion quite unnecessarily, and somehow the gap has to be bridged. It is enlarged by the action of the Royal College of Physicians in offering to cooperate with the Government by giving evidence to the Royal Commission—an action which recalls to the majority of the profession the 1948 betrayal

Firstly, let me restate the very basis on which our action rests and which you deny

1 The power of the Executive to do what it likes, for reasons of expediency, in dealing with what Lord Home describes as one of the "great skilled professions," must be broken

2 The policy of appealing to "the sense of fairness of British Governments" in "the knowledge that they were dealing with a profession which in no circumstances would use its political weapons" is completely barren because no such "fairness" exists

3 We are therefore left with two courses Either we take the Government to court, as they suggest, to get a "declaratory judgment" on the validity of the contract implied by Government promises on the Spens reports and the consequent Danckwerts judgment or we withdraw and negotiate a new basis for return (This time taking care that we get a written contract)

Secondly my criticism of your editorials is based on the fact that you accept with very mild criticism the autocratic arbitrary methods the Government as new employers "with no inherent virtues" (to quote Lord Home again) have used to date and expect us as a profession to sit down and do nothing about them Surely, Sir, this is destitute leadership? This is complete resignation without argument Do you really imagine that in spite of all the legal arguments (which you dismiss as being far too many) the profession can put any trust in your advice to be good little boys and accept what the Government (which is embarrassed) is doing? Do you think that assurances can get over two separate statements, only two weeks apart, made by the Government in Parliament

(*a*) That an increase for junior hospital staff will be negotiated through Whitley machinery

(*b*) That a flat 10% will be paid to junior hospital staff from a date to be fixed by the Government

Where in this is the sweet "prestige of a profession, whose strength lies in the merits of its case"? I suggest it is in your statement that you expect Sir Harry Pilkington will come to feel the need of one or two colleagues with a good background knowledge of the N H S or the profession (guaranteed non-medical, of course) This is the most monstrous statement ever made by the editor of a medical journal in any country At its very best it amounts to rank betrayal of the profession it purports to advise On what conceivable grounds could the medical profession submit to having its future determined by people "guaranteed non-medical of course"!

Thirdly, having expressed my fundamental objections to your approach and detailed the basic differences with the Government (which are not—in my opinion—anything to do with pay), let me suggest a workable agreement By the time this letter is published we may be faced with an interim award, made without consultation Let us together say that we do not want the award—we want a proper negotiated agreement (not a Royal Commission)—with an agreed basis for future negotiation and the setting up of agreed arbitration machinery for future problems In this way we may save the Government money (temporarily) and we may achieve—what is far more important than any pay claim—a proper mechanism for settling our differences if any, in the future

To enlarge on the results of what this might achieve A new conception of a National Health Service with the *medical* people who are working in it satisfied—the patients therefore better served and the auxiliaries not at loggerheads with the profession It would certainly allow the profession scope for presenting ideas for the better running of the service which might save the country vast sums, and which are at present hamstrung by the very *non medical* persons you admire so much

London, W C 1   J L McCALLUM

⁂ We should not expect much good to come of direct negotiations with the Government in which the profession's avowed object was to limit the power of the Executive At present the best hope of obtaining useful changes in the arrangements for remuneration is to persuade the neutral Royal Commission that they are necessary As for the non-medical membership of the commission, we should perhaps have made it clearer that the reaction of our remarks was slightly acid —ED L

SIR,—It is most disturbing that the British Medical Association, which professes to respect the consciences of its members, should be adopting the tactics of the big unions, where the headquarters policy must be pushed through regardless of the feelings of the minority.

The policies of phased withdrawal and of boycott of the Royal Commission, which seem to many unethical, were decided on by central committees of the B M A without knowledge of the views of the rank and file which could readily have been ascertained by a postal ballot Having failed to do this, it seems quite incredible that a professional organisation should then endeavour to get a mandate for the policy which they had already publicised in the manner I am about to describe

Last week at a meeting of my own division of the B M A I proposed that our local members should decline to support the G M S Committee's proposals I knew, of course, that it would be a difficult path to follow, as it always is when one is not blindly following the majority, but I did not anticipate that there would be present members of the B M A council and of the G M S Committee (neither of them members of our division) ready to spring to their feet every time a point was made against the party line In addition there was a member of the headquarters medical secretariat on hand to chide backsliders with gentle irony and even to question the sincerity of their views by scoring debating points like any other professional politician

All this, I may say, from an association which claims to spurn trade-union methods and at the same time complains that the Government has behaved like dictators!

If the original Negotiating Committee had negotiated terms of service in the years before 1948 instead of talking about principles until the eleventh hour, when they suddenly panicked, the Spens reports *could* have formed the basis of an agreement duly signed and sealed

BLACKLEG

SIR,—The time is obviously coming for a revision of the system of payment for general practitioners Those aspects of general practice which give personal satisfaction and which may involve philosophy and the "art" may be difficult to assess financially, but one might reasonably expect payment to be on the basis of efficiency

The most obvious injustice at present seems to be that efficiency in running a practice is usually associated with financial disadvantage

For example, a practitioner, who successfully runs a practice with one patient less in an acute hospital throughout the year than another practitioner with a similar list, is costing the National Health Service about a thousand pounds less

Some measure of practice efficiency from a business point of view could be obtained by considering in relation to the total numbers on the list

(1) The total certified days off work (obtained from the Ministry of National Insurance)

(2) The total prescribing costs (obtained from the Pricing Bureau)

(3) The number of inpatient days and outpatient appointments (obtained from the hospital)

By some sort of a points system in each of the above items taken respectively over a year, I feel sure that a payment in addition to ordinary capitation fees could be made, which would provide incentive to good practice and would in effect be a merit award to the good general practitioner

Workington R N R GRANT

SIR,—I am disturbed more than I care to admit by the current wrangle with the Government caused by the profession's 24% salary claim, though there are doubtless many worthy reasons why some feel justified in this claim

There is an atmosphere of wronged virtue in the profession's publications, which assumes that we have not broken *our* obligations to *the* Government, can we honestly say all doctors have done their work as they should in the National Health Service? In my opinion the answer is No I am not surprised the Government's attitude is unhelpful when so many doctors have abused the N H S

Before we press our claim further I believe doctors should come forward with a scheme embodying the much-needed reforms in the N H S I cannot agree that this is primarily the Government's obligation to us I would like to see the following incorporated

(1) General practitioners should be paid according to work done, not for the number of patients on their lists

(2) Patients should pay for treatment and advice up to a certain fixed annual amount according to a means test

(3) Diagnostic facilities should be made available to general practitioners

(4) Casualty departments should receive part time staffing at consultant level

Doctors' position of esteem has been won by service to the public without counting the remuneration If we take arbitrary action, as is at present recommended, we shall do ourselves a great disservice

Kettering EDWIN J WRIGLEY

ASEPTIC MENINGITIS

SIR,—I have seen several cases in Marche, in Central Italy, in 1955, with clinical features partly resembling those described by Dr Garnett and his colleagues and by Dr Rotem (March 9)

Between June and November, 1955, 38 patients with this illness were admitted to hospital in Urbino [1] [2] Many patients were from mountainous places (the Urbino area is mainly mountainous) and most of them were children and young adults There was no difference in sex prevalence The predominant signs and symptoms were fever, frontal headache, vomiting, photophobia, and neck rigidity

The cerebrospinal fluid (C S F) was under increased pressure There was a positive reaction for globulin and moderate increase in albumin, the number of cells was raised (20–1500 per c mm), with lymphocytes *predominant*

30% of our patients had rather different signs and symptoms In many cases the liver was involved, with abnormal function tests, 3 patients had nephritis and 1 herpangina 10 had signs of myelo encephalitic disorders (ataxia paresis of the limbs, lethargy, mental changes) Electrocardiographic examination often indicated myocardial damage of diffuse type, of which there was no clinical indication Wassermann and Paul Bunnell tests were constantly negative At the virus laboratory of the University of Siena, Coxsackie virus was isolated from fæces and C S F in about half the cases

Recovery was quick and complete in all except 1 patient who had severe *encephalitic manifestations* and died The virus was not isolated from this patient, but we presume, on epidemiological grounds, that *it* was present

Owing to the presence in our cases of disturbance related to different parts of the neuraxis (central nervous system), we have called this illness acute epidemic neuraxitis due to Coxsackie virus

UTERINE ELECTROLYTES IN PREGNANCY AND LABOUR

SIR,—In their article of April 6 Dr R L and Dr J H Cort drew attention to the possible occurrence of potassium depletion in pregnancy and suggested that an inadequate intake of potassium may have contributed to such a loss in their patients

It is likely that if potassium salts were given by mouth there would be a high proportion of digestive disturbance The concentrated orange juice provided by the Welfare Food Service for pregnant women in this country contains a considerable quantity of potassium Analyses of samples from several batches show that the concentration is of the order of 250 m eq per litre At present it is possible to obtain 1 bottle (171 ml) each week, containing about 43 m eq of potassium This is not a significant addition to dietary potassium, but it would be possible to achieve this if the dose were increased and with little likelihood of patient resistance

Obituary

THORVALD JOHANNES MARIUS MADSEN

Hon C B E , M D Copenhagen

DR Thorvald Madsen, who died on April 15 in Denmark, was long known in his own country as the head of the State Serum Institute In the rest of the world he will also be long remembered for his work with the League of Nations and later with UNICEF

He was born in Copenhagen in 1870 and he took his medical degree at the university there in 1893 A year later he became an assistant in the university laboratory for medical bacteriology In 1902 he was appointed head of the State Serum Institute Many scientists from all over the world were drawn to the Institute by his work on diphtheria toxin and antitoxin, and this was one of the subjects which he discussed in the lectures which he gave, in faultless English, to the University of London in 1929

His work for the League of Nations began after the 1914–18 war, when as chairman of the League's Health Committee he was faced with the task of containing the epidemics raging in Eastern Europe Cholera, typhus, and smallpox were being brought by refugees returning from Russia and Turkestan to the newly formed Eastern European States whose health services were still incomplete Through Madsen's administration the League was able to give timely and practical help to these governments and also to Greece, where severe epidemics had broken out after the return of refugees from Asia Minor In 1928 when dengue fever became rife in Athens the Greek government again turned to Madsen for advice, and with his help the health services of the country were reorganised

Dr Madsen had served so many countries so well that his record of international honours was as impressive as it was deserved In this country he was a member of the Society of Medical Officers of Health and the Pathological Society He was also an honorary graduate

Glasgow University, and a holder of the Buchanan edal of the Royal Society In 1921 he was appointed n honorary C B.E

N M G writes

Madsen was a great doctor for a much longer span of me than is usually given to men to be ' great " He won a ational reputation long before the first world war as head f the Danish State Serum Institute and an international ne between the wars as chairman of the Health Committee f the League of Nations Yet for some years after the second orld war he worked actively in the international field with NICEF, and even after he returned to Denmark his inquiring ind was constantly at work on the problems of his first love, pidemiology Only a few months ago I had a letter from im making some inquiries on the incidence of infectious isease in this country

Spare and very upright with bright blue Danish eyes and soft voice, he would when over eighty, run up the stairs o his office in Rome and arrive on the fourth floor in better ondition than the relatively young men with him In the vening you might find him dining and dancing at the Bibliotheke " and when we left him still dancing, at midight, he would cheerfully remark " See you in the office at 30 "

As chairman he was always courteous and unruffled and ad a special kindness for the younger members of the Health ommittee With the director, Dr Rajchman, at his elbow, e and his committee, which included men such as Buchanan, arisot, Cumming, Stampar, Lutrario, Jitta, and Velghe, laid he foundations of the work which W.H O continues today

STANLEY GEORGE JAMES

M.D Sydney, M R C.P , D.P M

Dr S G James, medical superintendent of Broadmoor Institution, died on April 11 at the age of 56

Dr James was born in Sydney and graduated M B from the university there in 1926 After holding resident appointments at Sydney Hospital he came to this country and became senior house-physician at the West End Hospital for Nervous Diseases, London. In 1931 he took the M R C.P and in 1936 the D P.M. He held appointments as assistant medical officer at Friern Hospital under the London County Council and as deputy superintendent to the Rampton State Institution, Retford, before he was appointed, in 1949, superintendent of Moss Side Hospital, Maghull

During the three years he held this post he established many contacts with his medical and psychiatric colleagues throughout the Liverpool region, and the value of his counsel and work to the region as a whole was recognised by his appointment as physician to the Liverpool psychiatric clinic

In 1952 he took up his post at Broadmoor where he quickly became popular with his staff and patients, and a colleague describes him as ' a strong advocate of modern forms of treatment and a delightful companion "

J E H, who knew him during his Liverpool years, writes

Quiet and unassuming and of great personal charm, Dr James possessed a profound knowledge of psychopathic states and the large psychiatric no-man's land between mental deficiency and psychosis His capacity for calm cool judgment combined with an equable temperament were qualities that ensured his outstanding success in his own chosen sphere His hobbies were cars, electronics, and work He will be greatly missed by his many colleagues and associates, not only in the Liverpool district but throughout the psychiatric world

In 1954 Dr James married Miss Winifred Boshier, at that time matron of Broadmoor

Births, Marriages, and Deaths

BIRTHS

BLACKSTOCK.—On April 20 at 1264 Coventry Road Birmingham, to Pamela wife of Dr A M Blackstock—a son Charles.

DORMANDY —On April 13 to Dr Katharine Dormandy (née Baker) wife of Captain T L Dormandy F.R.C.S E., R.A.M.C—a daughter

Notes and News

UNIVERSITY APARTHEID

NINETEEN vice chancellors and presidents of British universities and university colleges have joined in making a statement[1] of the policy of the government of South Africa towards the universities there[2] Having set out the main provisions of a Bill which was lately introduced into the parliament of the Union, they point out that, if such a Bill becomes law, the universities in South Africa will comprise the four Afrikaans medium universities (which admit only white students), the Universities of Cape Town and Witwatersrand (which will then be allowed to admit only white students) and the University College at Fort Hare and the Medical School for non Europeans in Durban, which will then be organised as part of the University of South Africa and controlled by the government

Such proposals, they say, are open to the gravest objections Firstly, it is contrary to the interests of university education that students should be completely segregated on grounds of race and colour Secondly, the proposed action is contrary to the expressed wishes of the Universities of Cape Town and Witwatersrand, where it is thought that both white and non white students will suffer Thirdly, " it is a very serious matter that university institutions should be arbitrarily dealt with by the Government of the day through legislative processes " Fourthly, substantial powers of control of the non-white colleges will be vested in ministers, the development of academic self-government will be prevented. Furthermore, it is provided that a member of the staff who publicly criticises any department of the government will be liable to discharge, this is described as " intolerable "

The statement notes that the Bill described has been withdrawn for technical reasons,[3] but says that the government has not changed its policy Apparently the provisions of the Bill are to be achieved piecemeal thus a Bill establishing segregation has been introduced in the present session, and legislation concerning Fort Hare and the medical school in Durban will be introduced later The signatories conclude -

" we would express the hope that this opportunity might be taken for further consideration of the academic implications of the policy which the Government is pursuing and of the manner in which it proposes to give effect to it "

MEDICINE AND THE MINES

TEN years ago the National Coal Board, which had been charged by statute with the duty of securing the health of its employees appointed a chief medical officer Since then the medical service has expanded till there is now a doctor (some times two) for each area, and the board employs 300 State-registered nurses and 2000 medical room attendants. An account of the service and its functions is given by Dr J M Rogan, the chief medical officer, in a new book[4]

Since 1952 all new entrants to the mines under the age of 21, and most of the older men, have been medically examined by the board's doctors This examination includes chest radiography Rescue workers, and those liable to skin cancer, are examined yearly Periodic radiography of miners is planned. The medical service also advises on hygiene (e g on dust suppression, ventilation, lighting, and underground sanitation) as well as on the medical aspects of safety and the resettlement of disabled men The doctors, nurses, and attendants help to train the 20,000 first-aid men.

The number of medical centres has risen from 8 in 1946 to 346 in 1956, allowing more efficient treatment of accidents and illnesses at work. Further treatment is normally provided by the National Health Service, except where there would be clear saving in time and convenience in treatment at the medical centre, and the family doctor has agreed to this.

Dr Rogan surveys medical topics which have specia relevance to the mining industry The occupational mortality of miners has steadily fallen since 1911, though it is still above the national average Research on pneumoconiosis is in progress, including a survey of its prevalence The incidence of beat disease (an inflammation of tissues near joints devital ised by repeated blows) does not diminish, but antibiotic treatment shortens the period of disability The incidence of nystagmus is falling as lighting is improved Fungus infection of the feet affects a third of the miners who use pit-head baths and a twentieth of those who do not, experiments are in progress with fungicidal foot sprays and fungistatic material incorporated in the floors of these baths Weil's disease is combated by unremitting destruction of rats, in the past ten years there has been one serious outbreak with 23 cases and 9 deaths

Research is carried out by the board's medical service itself, by the Medical Research Council (which has set up several units including the pneumoconiosis research unit at Cardiff), and by universities The board gives grants towards the cost of research

GENERAL MEDICAL SERVICES COMMITTEE

Dr Talbot Rogers has resigned from the chairmanship of this committee and Dr A B Davies has been elected in his place In a statement to the press on his resignation Dr Rogers said that in his view the doctors had now received from the Royal Commission sufficient assurance to make it possible "for us to deploy our arguments and put our whole case before them" His colleagues felt that, despite the exchange of letters with the Prime Minister and the Commission's statement on how it had decided to proceed, they still had not any real assurance that their views would be fully heard and cognisance taken of them

NUCLEAR-WEAPON TESTS

THE National Council for the Abolition of Nuclear Weapon Tests was formed to give expression to public concern about the continuation of nuclear weapon tests A leaflet has been prepared setting out some of the hazards of nuclear explosions and suggesting ways in which public opinion can express itself Copies of this leaflet (*2d* each, *8s 6d* per 100) and other information can be obtained from the secretary of the Council, c/o 29, Great James Street, London, W C 1

The Council has organised a meeting on Tuesday next, April 30, at 7 30 P M at Friends House, Euston Road, N W 1 The speakers will include Prof Joseph Rotblat, professor of physics at St Bartholomew's Medical College, and chairman of the committee of the Atomic Scientists' Association, whose statement appears on p 878

STRANRAER HEALTH CENTRE

THE first annual report of this centre, which was opened in May, 1955,[1] is the record of a successful beginning The second health centre in Scotland, it serves a small Lowland town and is an interesting and modest contrast to its elder sib at Sighthill

The Stranraer centre has five consulting suites for general practitioners The rent of each, fully furnished and equipped and including heating, lighting, cleaning, and nursing and clinical assistance, is £200 per annum It also accommodates the local authority clinics and has a room for minor surgery and a small laboratory As it is beside the local hospital, X ray and other services are available at all times and this has proved a convenient arrangement Nine doctors, in five firms, provide family doctor services and now have 13,551 patients on their lists The record service of the centre only got under way in September, 1955, but for the last eight months of 1955–56 the number of attendances at surgeries was 19,353 7437 patients attended clinics held by visiting consultants The local health authority holds a weekly child-welfare clinic, mothercraft classes, and an ophthalmic clinic The school medical service has a weekly minor ailments clinic Dental clinics for school children and the priority classes are held three times a week

In the first year, the reports says, all the doctors have become enthusiastic and none of them would now like to go back to the old system of practice The convenience of having X ray investigations and opinions, surgical opinions, and anæsthetists at hand has proved a boon both to doctors and patients The time saved by having a dressings room with a nurse in attendance has also been appreciated and the clerical and telephone help has been valuable The main deficiencies have proved to be the inadequacy of the office accommodation and the waiting space for patients requiring dressings After an initial suspicion lest they might be divorced from the doctor of their own choice, the patients are now strongly in favour of the centre, and a feeling of local pride in it is becoming manifest The report ends "It is thought that the advantages of modern equipment and personnel have been successfully grafted on to the old family tradition and that the intimate personal relationship which has always existed between doctor and patient in this area has not been disturbed"

CONTROL OF THERAPEUTIC SUBSTANCES

UNDER the Therapeutic Substances Amendment Regulations 1957, which come into force on May 1, the following substances are added to the first schedule of the Therapeutic Substances Act, 1956

(*a*) Any absorbent or protective material capable of being absorbed by the body tissues which is offered for sale for use in surgical operations

(*b*) Tetracycline, polymyxin B, and viomycin (or preparations containing them) which are intended for parenteral injection

(*c*) Hyaluronidase, streptokinase, streptodornase, and streptokinase streptodornase (or preparations containing them) which are intended for parenteral injection

(*d*) Heparin and preparations thereof

(*e*) Corticotrophin and preparations thereof

The regulations (S I 1957, no 550) also modify and amend the requirements for preparation and testing of various substances including B C G vaccine, smallpox vaccine, poliomyelitis vaccine, antibiotics, serum albumin, and surgical materials

CARCINOGENS IN TOBACCO

AT a recent meeting of the American Institute for Cancer Research, Dr E L Wynder, of the Sloan Kettering Institute New York, reported experiments on the carcinogenic effects of tobacco tar on the skins of mice[1] He had removed the waxy coating of the leaves and stems, using hexane as a solvent A solution of the tar obtained by combustion at 880°C was painted on the skins of mice A 5% solution of the tar derived from the waxy coat produced carcinoma in 23% of the mice in five months, but a 50% solution of the tar derived from the dewaxed leaves produced only one carcinoma (the report does not specify the number of mice used) after a year Dr Wynder also said that tar obtained by burning at 720°C (which he gave as the temperature of tobacco burning in a pipe) had much less carcinogenic action than tar obtained by burning at 880°C (the temperature of a lighted cigarette) He had found that filter tips did not selectively remove carcinogens,[2] though the report of his remarks implies that an efficient filter may possibly reduce the total amount of tar inhaled

OUR FELLOW CREATURES

THE ascetics of the Jains, an Indian sect, sweep the ground before them as they walk, lest they crush any living creature The Christian religion has seldom been interpreted as requiring such action, but Major C W Hume, director of the Universities Federation for Animal Welfare, thinks that the Church ought to do more to promote the well being of non human animals The founder of the Royal Society for the Prevention of Cruelty to Animals was an Anglican priest, but even today the Church of England has taken no official cognisance of animals' rights indeed, "during the past thousand years consideration for animals has, on the whole, lain outside the Christian theology"

In his little book, *The Status of Animals in the Christian Religion*,[3] which is illustrated by Fougasse with his wonted charm and wit, Major Hume traces the attitude of Christian Churches from the earliest times He suggests a practical programme for the Church of England, ranging from additions to the liturgy and the hymnals to the laying down of rules of conduct that would condemn, for example, the atrocious cruelty of much trapping (he estimates that a musquash coat costs up to 7 months of extreme suffering directly comparable to that of crucifixion and breaking on the wheel), and inhumane methods of slaughtering animals for food "The major cruelties practised on animals in civilized countries today arise out of commercial exploitation"

Major Hume's book is distinguished by clarity of thought lack of sentimentality, and much scientific and theological learning presented in an engaging fashion He allows that killing may be necessary (e g, of vermin) but points out that this need not involve hatred and should be done as painlessly as possible He makes clear the moral difference between killing and hurting, thus he says that men are more important than animals, and killing a man is therefore more important an killing an animal, but hurting an animal is just as ong as hurting a human He answers Auden's criticism that loving birds is easy but it's hard to love the louse," showing that love must be understood in terms of behaviour ther than feeling His attitude to experiments on animals is oderate and commands respect, medical men will be rticularly interested in what he has to say about scientific ethod

PEPTIC ULCER AND INDUSTRY

In 1955, the British Council for Rehabilitation set up special working party, under the chairmanship of Dr Avery Jones, to "consider the problem of the peptic ulcer industry" The working party has now issued its report[1] hich briefly summarises what is known about peptic ulcer is desirable, the report says, for each patient to coöperate ith the doctors, and for each canteen to provide a palatable ght meal as an alternative for those who need it, and ght-shift work may be harmless in individual cases, if there a canteen The report is intended to guide industrial anagement and personnel officers

BEDWETTING

A new addition to the booklets published by the National ssociation for Mental Health in their parent-guidance ries is a straightforward account of enuresis by Dr Portia olman[2] Its opinions are orthodox and judicious What arents of bedwetters seldom understand is that enuresis common, has many causes, and is not a sign of laziness or aughtiness which can be overcome by discipline or will-ower Dr Holman makes it clear that there is no quick and mple remedy and that much patience is needed Her advice ill prove helpful to many, but the dangers in writing for ymen have not been entirely avoided. Having read this ook, parents will expect their own doctor, whom they are roperly advised to consult, to approach the problem on the nes suggested, and the authority of the written word may etract from, rather than reinforce, the doctor's spoken ord The case histories may encourage attempts at differ ntial diagnosis by parents, but they will do much to help in he better understanding of enuresis

OCCUPATIONAL THERAPISTS

To celebrate its 21st birthday the Association of Occupational Therapists held a reception in London on April 12 in the hall of the Goldsmiths' Company, to which it has long been indebted for interest and support With 1774 members, the association awards a diploma to students from the seven recognised training schools in London Oxford, Liverpool, Chertsey, Derby, Exeter, and Northampton, and it works closely with the sister association in Scotland in the Joint Council of Occupational Therapists of Great Britain, through which both countries are represented in the World Federation of Occupational Therapists

The guests were received by Mr L G Allbon and Miss M L G Bunting, chairman and vice chairman of council Lord Amulree, F.R C P, the president pointed out that occupational therapy dates not from 21 years ago but from prehistoric times, and is now seen to be indispensable to medicine Dr Janet Aitken, as a past president, said that though occupational therapists are increasing faster and faster, the increase is not nearly fast enough great needs are still not met notably in mental hospitals Mrs Glyn Owens, principal of the Liverpool School, who (as Miss Constance Tebbit) was first principal of the pioneer school (Dorset House) established by the late Dr Elizabeth Casson at her psychiatric clinic in Bristol, spoke of occupational therapy's debt to Dr Casson and paid tribute to many others who have made the history of the association, including Sir Hubert Bond, its first president The first occupational therapy department to be opened at a London hospital started in 1938 at the Royal Free when Miss Muriel Tarrant, now co principal of the London school, was given charge of it on the understanding that she would also supervise the diet kitchen One of the early students at Bristol was Miss E M Macdonald, the present principal of Dorset House which is now at Oxford

On the following day the association held its annual meeting when Dr J G Sommerville presided at a brains trust on the Piercy report on rehabilitation of the disabled

MALARIA IN THE BALKANS

In March, 1957, the second malaria conference for South-Eastern Europe was held in Belgrade In all countries in this area and in the Soviet Union, malaria is receding rapidly —even in Greece, the only country where mosquitoes resistant to insecticides have appeared All these countries expect to eradicate the disease in 3–5 years It is hoped to achieve this at about the same time in all the countries, to make frontier prophylaxis and quarantine unnecessary

Several reports from individual countries emphasise the economic benefits of malaria control thus in Greece malaria used to cost the country 80 times more than it does now In the Soviet Union and some other countries treatment is compulsory

ANNALS OF PHYSICAL MEDICINE

The journal of the British Association of Physical Medicine, which is edited by Dr A C Boyle, is now published by Messrs Baillière, Tindall, & Cox It has been restyled and the format enlarged The first issue of the new volume contains the first in a new series of revision articles The *Annals of Physical Medicine* is published quarterly Subscriptions (30*s* or $5 50 annually) should be sent to the publishers, 7, Henrietta Street, London, W C 2

University of Oxford

Dr E D Acheson has been elected to a Radcliffe travelling fellowship

University of London

On March 27, the following degrees were conferred

M.D —E A. Boyse, Margaret R Dix, P W G Tasker
M S —W J Atkinson

University of Manchester

On May 15 the honorary degree of LL.D is to be conferred on Sir Geoffrey Jefferson, F.R S

Royal College of Physicians of London

On April 15, Dr Robert Platt, professor of medicine in the University of Manchester, was elected president of the college

Royal College of Surgeons of England

Dr D J Lyle, lecturer in neuro ophthalmology at the medical college of the University of Cincinnati, will deliver the Moynihan lecture on Wednesday, May 8, at 5 P M, at the college, Lincoln's Inn Fields, London, W C 2 He will speak on the causes and treatment of exophthalmos

Royal Australasian College of Surgeons

Alan Newton prize —The subject chosen for the next award of this prize is the surgery of malformations of the heart and great vessels Candidates must hold an Australasian or British fellowship in surgery, and the closing date for entries is Dec 1, 1958 Further particulars may be had from the secretary of the college, Spring Street, Melbourne, C 1

The prize for 1956 has been awarded to Mr L I Parton of Auckland Mr C R Davidson, of Ballarat, *proxime accessit*

University College of the West Indies

Dr Robert Mitchell has been appointed lecturer in anatomy

Sanderson-Wells Lecture

Mr R F Milton, PH D, will give this lecture on Tuesday, May 21, at 4 P M, at the Middlesex Hospital, London, W 1 He is to speak on trace elements in the biological relationship *of soil, plant, and animal*

Faculty of Homœopathy

A meeting of the faculty will be held at the Royal London Homœopathic Hospital, Great Ormond Street, W C 1, on Thursday, May 2, at 8 P M, when Dr James Connor will speak on homœopathy and obstetrics

Biochemical Society

A meeting of this society will be held in the department of biochemistry of the Physiology Institute, Newport Road, Cardiff, on Friday, May 24, at 2 P M

Pharmaceutical Society

Dr William Lane-Petter, director of the Laboratory Animals' Bureau of the Medical Research Council, has been appointed by the Privy Council a member of the council of the society in succession to Dr J A. Giles who has retired

Mental Retardation and Epilepsy

Dr D A Pond and Dr B H Kirman will speak at a meeting on this subject to be held at the Fountain Hospital, Tooting Grove, London, S W 17, on Tuesday, April 30, at 5 30 P M

World Health Organisation

The U S S R has informed the World Health Organisation of its decision to resume active membership as from the current year The U S S R became a member State in March, 1948, but in February, 1949, discontinued active participation

Neurotics Nomine

About a year ago some ex-patients, patients, and other people interested in nervous and mental illnesses formed this group They are holding their first public meeting at Caxton Hall, London, S E 1, on Monday, April 29, at 7 30 P M , when Dr Joshua Bierer will be in the chair

Royal Commission on Doctors' and Dentists' Remuneration

Any person or organisation wishing to submit evidence to the commission is invited to send a written statement as soon as possible to the secretary of the commission, 10, Carlton House Terrace London, S W 1

Royal Society of Health

Nearly 50 foreign and Commonwealth countries will be represented at the annual congress of this society which is to be held at Folkestone from April 30 to May 3 The Soviet Union will be represented by Prof Viktor Zhdanov, a deputy minister of health, and Chile is sending its minister of health and social service The subjects for discussion include smoking and drinking among school-children , shortage of dentists , emigration of doctors , fluoridation of water-supplies , world health , irradiation of food , effect of the hire purchase system on mental stability , marriage hygiene, tall buildings , and the dangers of cracked pottery

Medical Art Society

The annual exhibition of this society will be held at Walker's Galleries, 118, New Bond Street, London, W 1 from Friday, April 26, to Saturday, May 11

London Medical Orchestral Society

This society will give a concert in aid of the Imperial Canc Research Fund on Saturday, May 18, at 8 P M , at the Royal College of Surgeons, Lincoln's Inn Fields, W C 2 The solo will be Miss Liza Fuchsova, and the programme will includ works by *Beethoven, Schubert, and Schumann* Tickets (10*s* , 7*s* 6*d* , 5*s*) may be had from the hon secretary, 6 Oxford Court, Queen's Drive, W 3, or at the door

Prof Robert Kellar is visiting New Zealand and Australia during June, July , and August as the guest lecturer of Auckland University College and the Australian Postgraduate Federation in Medicin

At a meeting of the National Smoke Abatement Society held in London on April 11 it was unanimously agreed that the society should seek incorporation as a company limited by guarantee and without share capital, and with the new name ' National Society for Clean Air '

The meeting of the Dental Implant Society of Great Britain on Wednesday May 15, at 1, Wimpole Street London W 1 will begin at 7 30 P M (not at 7 P M)

Some Medical Problems as they affect Adoption Practice —Copies of this report of the Standing Conference of Societies Registered fo Adoption may be had from the hon secretary Mr A Rampton Gort Lodge, Petersham, Surrey (2*s* 6*d* post free)

CORRIGENDUM *Antigen antibody Responses in Multiple Sclerosis* —*In our annotation of April 13, the second paragraph* should begin .

" Another slant is suggested by a preliminary report from Honor Smith and her colleagues[12] on studies at Oxford which show that on intrathecal injection of tuberculin, sensitised (Mantoux positive) patients with multiple sclerosis react differently from otherwis *normal subjects* [not other patients with the disease] "

THE NORMALITY OF AGEING

THOMAS RUDD
M D Lond , M R C P
CONSULTANT PHYSICIAN, TIVERTON HOSPITAL, DEVON

THOUGH it is a truism that old age is a natural state, the truth of this evident fact is not always recognised Old age, it is generally agreed, is inevitable, subject to the chances of mortality That it is also natural is less generally accepted If old age is unnatural, then old age is a bad thing, as bad for others as for ourselves, and the origin of resistances and resentments in the human mind The unnaturalness of old age, as generally conceived, places a barrier between the age-groups

In our moments of calm reason we admit that the barrier is imaginary But the important thing, psychologically, is that it is so often imagined And not only do we thus split off old age, as a separate part of life, a kind of postscript or appendix, but we try to do something similar with the other end of life when we split off childhood and adolescence as phases for special treatment, the nature of which is decided by those of us who, in middle life, govern affairs, and call the tune, even if we do not always pay the piper This splitting of life into hard and-fast compartments is at once unhistorical and unpsychological, making no allowance for human individuality Social historians can perhaps trace its origin in the past two hundred years The injustice and tragic consequences of making children and adolescents fully responsible for their actions have made the pendulum swing too far the other way Adults now decide what is fit and proper for people at the two extremes of life It is no wonder that the old sink into apathy while the young express their unfulfilled and frustrated powers in reactions and delinquencies

Psychological development through life is difficult enough at any time, and the modern tendency to split people into children, adolescents, adults, and the elderly places a further obstacle in the way of normal mental progress More unfortunately still, it allows the mature adult, from his point of vantage, to react emotionally to the other groups Children become "kiddies" to be pampered and denied the responsibilities they crave, while the aged become "old folks" to be patronised and amused The result is irritating to young and old alike and arouses much resentment for the adult, the effect may be tragic, because his attitude splits him off from the natural development of man through the stages of life, each one of which is necessary for the complete maturation of the personality

* * *

A safe journey to normal and happy old age is not easy Anyone with experience of children, or having insight into his own mind, recognises the psychological difficulties inherent in growing up, and indeed in passing from any stage of life into the next We cling, not unnaturally, to what we have, to the safety and comfort of the present, and draw back from the unknown tomorrow, with all its possible dangers The child, however much it may long to spread its wings, enjoys the advantages of shelter and may cling to childish attitudes, even when the responsibilities of early maturity are offered The child may well be afraid of life, but many years later when it has accustomed itself to responsibility it may be reluctant to surrender it The fear now is not of living but of renunciation and of dying As Jung says "His neurosis comes mainly from his clinging to a youthful attitude which is now out of season,"[1] and the basic fear derives from the false premise that only the mature state is desirable, and that old age means only decline and waiting for death

This fear colours the approach of many mature people to their future and their attitude to older people Their reaction may be one of pity, expressing itself in patronage, or it may show itself negatively in resentment and the desire to brush the unwanted aside It is important that these false attitudes should be recognised in ourselves and in others, because of their power for harm, not only in the home but in medical and social care, as well as in industry

Psychological development, though often both difficult and painful, is generally achieved to a greater or lesser degree by most young people But the passage to healthy old age is less often satisfactorily made The promises of maturity are glittering enough to the adolescent to make the adventure into manhood or womanhood attractive The promised joys of old age are considerably less inviting to the materialist which is in most of us It is not surprising that many of us "stick," unaware that, by refusing normal development and clinging to outgrown attitudes, we are inviting frustration

This difficulty has been created by man himself When a civilisation places so great an emphasis on material success, puts the zenith of life in the sixth decade, and refuses employment to anyone past the middle 60s, it produces old people who have been split off from the main stream of life, and a mass of neuroses among those who are still active but who dread being relegated to the have beens

* * *

As a result of this approach life has become truncated, as it were, in the 60s, after which useful development is restricted and the value of life denied Such an attitude is contrary to the Christian conception of the wholeness of life every stage of life should be characterised by its own appropriate activity, each has its own lessons to be learnt, its own contribution to make to communal life, as well as its own dangers to be faced The activity of infancy is not that of later childhood, nor is that of adolescence the same as that of maturity Anyone occupied in the activities of age groups other than his own shows up his own abnormality Progress in development is made by surrendering the attitudes and characteristics of the former stage for those of the succeeding one Old age has its own characteristics, and it is the old people who show only characteristics of the earlier age groups that should be regarded as the "abnormals"

The instincts of self-preservation, power, and reproduction properly dominate the middle stages of life when children have to be reared As the child's dependence lessens, the strength of these instincts in the parents should also wane Ambition dwindles, things of the moment seem less vital, and present experiences are viewed in the light of past events Old age thus becomes a period of toleration and tranquillity Opinions are not less strongly held, but they should be held with greater toleration than in maturity It is, however, clear that this mellowing and broadening of understanding does not always come Instead, things are held so lightly that they are despised, nothing is considered good or worth while, and life itself peters out in bitterness and disillusion However common this reaction may be, it is still abnormal, and must not be accepted as a norm for old age

Old age challenges mature man to give up middle aged attitudes in favour of more seasonable ones If the challenge is faced squarely, the attitudes of old age will bring with them a new and different kind of happiness, as the assertions of maturity die down But if the challenge is not accepted, the whole of life becomes blighted Romano Guardini gives a picture of can tankerous old age "Beyond the mere drifting towards the end lies nothingness, dark, empty horror To save himself from it, the old person grasps at the nearest thing, this special food, that particular armchair, his bank account, his having the last word at home"[2] This state, however, is not the result of growing old but of refusing to grow up

---

[1] Jung C G Modern Man in Search of a Soul London 1945, p 17

* * *

It is impossible for us to look on old age except in terms of our own ageing, our approach is determined, for good or for ill, by our conception of our own future Man in maturity is inclined to view his future old age, and that of the present older generation, in one way Old age, on the other hand, may view itself differently Successful social work depends largely on bringing together these diverging viewpoints Old age's view of itself may be entirely correct, but the view of the younger generation is none the less important for two reasons In the first place, the kind of old people the young will become will be the direct outcome of their attitude to their own future Secondly, the helplessness of many old people today places them at the mercy of wage earners who may be not only their sole supporters but also their planners, legislators, and administrators

It is therefore doubly unfortunate that middle life so commonly looks on old age not as a challenge but as a threat As has already been said, if the challenge is consciously faced, and its implications worked out and accepted, only good can result But if the issues are evaded and repressed, the potentiality for harm is enormous This explains the undesirable attitudes towards old age often seen today in the individual and the community the antipathy which looks on old age as dirty and repellent, to be avoided at all costs, and the aged themselves as better dead, the self-pity which emotionalises old age, and tends to spoil good works by sentimentality, the patronage, which fundamentally despises old age and which tries to help in only material ways All these approaches fail because they deny identification between young and old, the helper and the helped, and refuse to recognise old age as a normal state Identification between individuals is often harmful, but identification between age groups, such as the mature and the elderly, is essential for successful case work Its absence is responsible for ill attended old people's clubs and and visiting To say "There but for the grace of God, go I" is to utter a characteristic Victorian feeling It goes nearer to the heart of truth to exclaim, with John Donne "Any man's death minishes me, because I am involved in mankind, and therefore never send to know for whom the bell tolls it tolls for thee"

When maturity views old age, then, it often does so with a disfavour which may be so deeply rooted as to persist into the viewer's own old age Healthy normal old people, however, look on themselves in a different way They are often only too aware of the physical limitations which prevent them striding over the moors, and meeting the fierce competition of existence, and which may be great enough to prevent any useful activity The personality can, however, remain surprisingly intact, and be, to the individual, his most cherished possession Miss Margery Fry,[3] gave a wonderful description of the feelings which so many older people share "To the administrator an individual may be just 'that old woman, I think her name is Jones,' but to herself she is the Katie Jones who won a prize for scripture and had the smallest waist in her class—with a thousand other distinctive features—who just happens to be old" Is it any wonder, then, that people who have, throughout their lives, grouped themselves into societies and clubs, according to their interests and achievements, should object to being classified into undifferentiated old people, *on* the sole ground of the disability they share in being old ?

To retain one's personality, and the respect attached *to it, is one of the great desires of old people* It is all the more regrettable that personality should be so commonly disregarded by younger people who have charge of their elders in hospitals and residential homes A man or woman who has borne an honoured name, in however humble a sphere, has surely the right to be called by it, even if his legs are too frail to carry the weight of his body even if breath is short and memory failing, he has surely some right to a say in arrangements made for his care The ability to choose, so important to us throughout life, does not fail as years creep on, and its denial to the old is prejudicial to their happiness and to their mental health So often choice in the greater things of life is impossible, only one place of abode or set of attendants may be possible But minor choices may be offered and provide minor, but worth while, satisfactions All who care for the older generation should ponder on this, and consider whether alternatives between the little things of life, between tobacco and sweets, tea or coffee, this or that chair can be arranged to enliven the monotony of living

Moreover many, indeed most, aged people have their own approach to religion for which they can demand respect, even if it is a matter they will not readily discuss with their somewhat preoccupied juniors False attitudes to religion in old age exist, as they do at other times of life most workers are familiar with the egotism and fears of senile neurosis, with the constant complaints of the grumbler who projects his self dissatisfaction on to his surroundings, and, above all, with the apathy—the Seventh Deadly Sin of Religious Sloth which in the middle ages was called accidie The characteristics of true religion in old age are as clear and definite as its characteristics in childhood and maturity They comprise a sense of true proportion, a valuation of material things at their true worth, and a greater tendency than formerly to view events *sub specie aeternitatis*

* * *

But though old age is a normal stage in life, as necessary as any other to human experience, and having its own problems, challenges, hazards and possibilities, it can be a time of disability and deterioration which frustrates happiness, and indeed any useful purpose—physical, mental, or spiritual All the same, the gross deteriorations of physique and mentality so often seen are the abnormal state and not the normal Only too often, moreover, they are the result of wrong methods of living and of thinking, in earlier life The ill effects of unwise eating and drinking are well known, although it is insufficiently appreciated that excessive intake of starches and sugars is as great a national problem as the overuse of alcohol Obesity, with its sequels of high blood pressure and diabetes, is a killing disease Smoking gives rise to lung ailments, including chronic bronchitis and cancer, and air-pollution in big cities and factories introduces another hazard Perhaps even more important are the neurotic fears to which the present age is a prey They are fundamental in producing, not only the frank anxiety states, but psychosomatic conditions of stress, such as gastric and duodenal ulcer, asthma, and high blood-pressure These groups of disease are responsible for a large proportion of illness in old age Even senile dementia, formerly thought to be caused by hardening of the cerebral arteries, is now held often to have an emotional background Gitelson,[4] summarising original work based on pathological studies, writes "Elderly patients, with more or less balanced personalities, are able to withstand a considerable amount of cerebral damage, while less-balanced personalities may produce a frank psychosis with a minimum of cerebral pathology. It seems to be the case that cerebral organic pathology is only a final precipitating factor in persons already excessively burdened by such emotional problems." It is, moreover, important to realise that just as anxiety and fears may affect physical and mental health, the opposite is equally true. As Paul D. White[5] points out: "We have paid perhaps undue attention to the harmful effects of fear, sorrow and anger. It is quite certain that biologic effects also result from cheerfulness, optimism, courage and joy." Though disability and ill health in old age are not entirely preventable, healthy living in the mature years will help to preserve health later, while a philosophy of life which excludes fears and anxieties and which teaches patience and cheerfulness is likely to prolong useful living.

* * *

The problem now arises of how to use the time afforded to us, when the productive years are over, and physical capacity is greatly reduced. If old age is a normal phase, what activity is appropriate to it? There are lessons to be learnt, some special to the time of life and some which should have been learnt earlier.

Willingness to renounce is perhaps the prime (and often the hardest) lesson to learn, including as it does not only the surrender of responsibility and authority, normal to maturity, but also the gradual loss of companionship of one's own age group, the impairment of vision, hearing, and powers of movement and thought. Against this background of renunciation the mind becomes detached from material things and each individual finds a meaning of life valid for his personality. In this mental development, which, for most people at least, cannot take place until old age is reached, lies the value to the community of its older members. The wisdom of simple experience can leaven the whole community, and show that the meaning of life transcends material success and ambition, and that true happiness is independent of both. A community without these values is poor indeed.

To regard old age as the stepping stone to eternity is the last and the great reorientation that we have to make in our approach to life, for as Monsignor Baunard points out: "notre vieillard à nous n'est pas un mortel qui finit, c'est un immortel qui commence,"[6] and this fact revolutionises our view of what we now see, not as a decrescent phase, but as a stage of life of supreme and immortal importance.

[6] Baunard, M. J. Le vieillard. Paris, 1926; p. 8.

"Though three generations can muster more resources than two, there are still many essential services which no family can possibly provide for itself. Few grandmothers can perform operations or teach algebra. Few grandfathers can, on their own, maintain children stricken by illness or unemployment. Children unaided, cannot support their parents through the years of retirement. The family is not a society on its own, merely part of the wider society, and, if it is to perform its proper function within its own sphere the family needs the support which only the wider society can give. This vital support the social services in some measure already supply. The health services have made a great and obvious difference to the well being of the family, especially to mothers and children. Old age pensions, inadequate though they often are, have enabled children to care for their parents all the more effectively. . . . The social services have in many ways already made the family of three generations or two not less, but more, viable."—MICHAEL YOUNG and PETER WILLMOTT. *Family and Kinship in East London.* London, 1957; p. 160.

A HEPARIN PREPARATION WITH PROLONGED ACTION

ITS CLINICAL APPLICATION

IN the treatment of thrombo-embolic conditions with anticoagulants, it is important to prolong the clotting-time as soon as possible and to retain this effect for a suitable time.

The coumarin derivatives are valuable because they are effective when administered orally, but at least 24 hours must elapse after the first dose before the clotting-time is increased sufficiently. When dicoumarol—in many respects one of the most convenient of these drugs—is given, the full effect is not reached for 48 hours, and sometimes longer. On the other hand, heparin given intravenously attains the full effect almost immediately, but this effect is rather short lived; usually it lasts 1–4 hours, depending somewhat on the dose. Hence, to maintain a sufficient increase in the clotting time, intravenous injections must be given at intervals of about 4 hours. To cover the time till the effect of a starting dose of dicoumarol has developed, eight to twelve intravenous injections must be administered, which is cumbersome. Intravenous drip infusion necessitates frequent determinations of the clotting-time, and the infusion-rate will have to be varied to obtain a smooth effect. The method demands experience and constant supervision. Using subcutaneous injections of concentrated solutions of heparin, a longer but also comparatively weak and variable effect has been obtained, and hæmatomas may arise on the site of injection (Raaschou et al. 1954). Intramuscular injections of aqueous solutions of heparin may cause large hæmatomas, which may remain unrecognised for some time, even causing anæmia.

Long-acting Heparin Solutions

One method of tackling this difficulty is to prepare a solution with prolonged effect for intramuscular injection, by dissolving the heparin in a 15–30% solution of gelatin (Pitkin's menstruum). But the viscosity of this solution is so high that it has to be warmed immediately before the injection and wide bore needles must be used. Moreover, the sterilisation of gelatin solutions is so difficult that it is better to avoid the use of this substance. But it would be rational to use other hydrophilic colloids which can safely be sterilised without being denatured.

Tonnesen and Pedersen Bjergaard (1950) have shown that the absorption of chorionic gonadotrophin is delayed when carboxymethyl cellulose has been added to the injection. In accordance with these observations, we tried to prepare a heparin preparation for intramuscular injection, and found that an aqueous solution of 1.25% carboxymethyl cellulose, after autoclaving, has a suitable viscosity. The pH of the autoclaved mucilage is regulated to 7.2 by means of a normal sodium hydroxide solution. Heparin is then added to the solution to give a concentration of 100 mg. (10,000 international units) per ml. The solution is heated for 15 minutes at 100°C. It is perfectly easy to inject intramuscularly through a long needle of narrow gauge.

Experimental Results

Before using the preparation for treatment we tested it in six healthy volunteers—four medical students and two young men who had recovered from slight acute diseases not known to influence blood coagulation Each was given 2 ml of the preparation once (equal to 200 mg heparin, or 20,000 international units) The injection was given intramuscularly in the gluteal region Blood samples were drawn just before and 2, 4, 8, and 24 hours after the injection The clotting-time was determined by the Lee-White test (fig 1)

The clotting-time had risen markedly after 2 hours, and a little further after 4 hours, after 8 hours it was still higher than normal The longest clotting time 2 hours after injection was 56 minutes, the normal was 5 minutes (before injection) In all these experiments the clotting-time at 4 hours was longer than at 2 hours, the longest being 58 minutes In five of the volunteers the longest clotting-time was between 30 and 58 minutes In the sixth the longest was 16 minutes 8 hours after the injection the clotting time was still much prolonged—in the first five subjects to between 18 and 27 minutes, and in the sixth to 11 minutes—still considerably longer than the pre-heparin time of 5 minutes

In the four persons who continued their usual work, there was some tenderness at the site of the injection which began after 5–6 hours The next day the tenderness had completely disappeared In the two who stayed in bed during the trial, no tenderness at all was felt

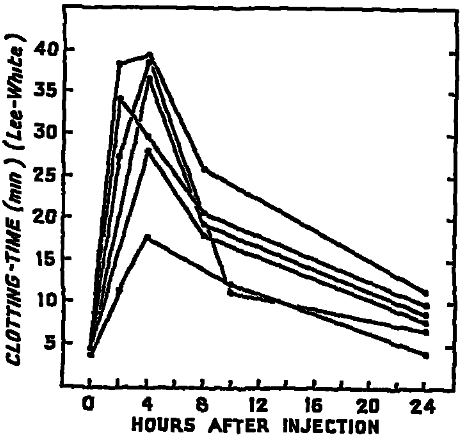

Fig 1—Clotting-time before and after intramuscular injection of 2 ml heparin prolongatum in 6 normal subjects

Clinical Trial

Since this preliminary test, we have used heparin prolongatum in almost all cases in which anticoagulant treatment has been employed It has been given in doses very roughly adapted to the estimated weight of the patient The initial dose has usually been 2 ml, followed by five 8 hourly injections of 1 ml each Obese patients have had the same initial dose, but the subsequent doses have been 1 5 ml In underweight patients the initial dose has been 1 5 ml and the subsequent doses 1 ml

Dicoumarol in doses of 300–600 mg was given at the same time as the first heparin injection No further dicoumarol was given for at least 72 hours The use of heparin prolongatum was started in February, 1955 Up to Dec 31, 1956, one hundred and thirty-five patients had been treated with heparin prolongatum, and altogether well over eight hundred injections had been given In no case was there any local reaction, tenderness, or infiltration, and no hæmatomas were observed

In forty-eight of the patients, altogether one hundred and seventeen blood samples have been drawn for Lee-White tests The patients tested were chosen at random. Thirty-one samples were drawn before heparin was administered Clotting times varying from 3 to 8 minutes were found, the vast majority being 4–5$^1/_2$ minutes, only four were below 4 minutes and three above 5$^1/_2$ minutes

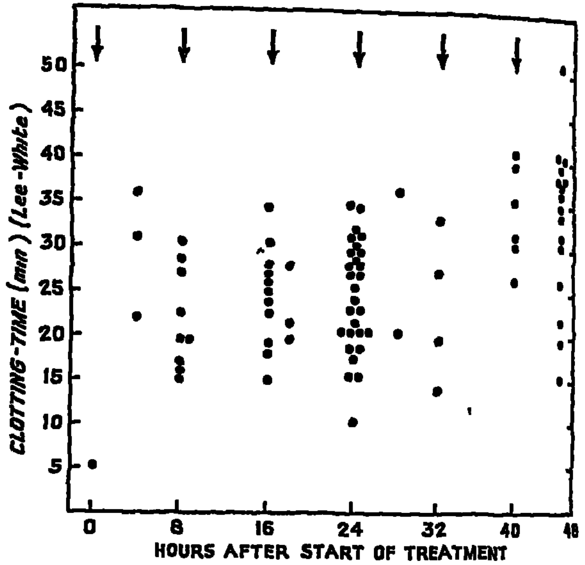

Fig 2—Clotting-times in random patients under treatment with intramuscular injection of heparin prolongatum (see text) Arrows mark times of injections

The remaining eighty-six samples were drawn 4, 8, 16, 24, 32, 40, and 46 hours after the first dose of heparin prolongatum The samples at 8, 16, 24, 32, and 40 hours were drawn immediately before the next dose on the schedule was given, the samples at 4 and at 46 hours were drawn 4 hours after the first and 6 hours after the last dose respectively Fig 2 shows that the clotting time is much prolonged in all samples, but, as could be expected, the times vary considerably, the lowest being found at 8, 16, 24, and 32 hours—i e, immediately before the next dose on schedule At 40 hours—also just before a scheduled injection—the times seem to be a little higher, possibly because the dicoumarol given at 0 hours has begun to have some effect These samples seem to show that on the whole a suitable effect was attained In two cases the clotting-time was followed for the whole period of treatment with heparin prolongatum (fig 3) The clotting-time was evidently much prolonged, and fairly constant values are found for the whole period

We have no established knowledge of what should be the *therapeutic level* of the clotting-time to prevent new thrombosis and impede the growth of thrombi already formed Indeed, it is probable that the optimal level differs under different conditions It will depend on the condition of the vessels (especially that of the intima of the vessels in which thrombosis is to be prevented), and on the rate of the blood-flow and all factors influencing this It is obvious that, by and large, the prevention of thrombosis in the venous part of the circulation would

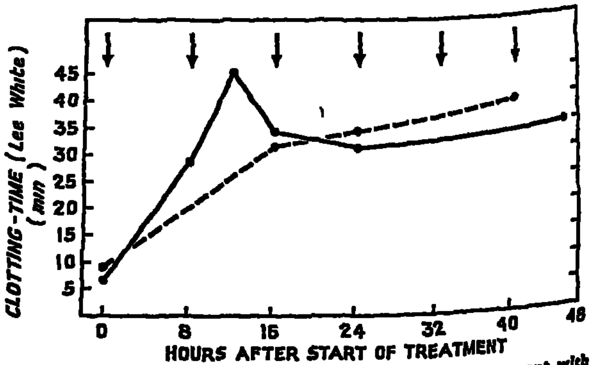

Fig 3—Clotting times in 2 patients followed during treatment with intramuscular injections of heparin prolongatum Arrows mark times of injections

emand a greater prolongation of the clotting-time than ı the arterial part Thus no optimal level suitable for all onditions can be decided On the other hand it must e kept in mind that too big doses involve a very real sk of hæmorrhage

It is a more or less accepted rule that the normal e , pre treatment) clotting-time must be prolonged no ss than three times to attain the "therapeutic level" his rule may not have sufficient factual and statistical ackground, but will serve as a practical guide until ufficient evidence for defining a correct therapeutic level an be procured

Without discussing them at length, we should mention hat heparin has actions other than prolongation of the lotting-time Important qualitative and quantitative ffects on the platelets and a notable action on the clotetraction are well recognised, but little is known of heir importance in thrombo embolic conditions Other ctions of heparin (i e , on the lipids and lipoproteins) are lso known, and they may also be important in these onditions

Our main object has been to prepare a heparin solution or intramuscular injection with long-continued action out without the risk of causing local reactions and hæmatomas On the strength of the observations here elated, we believe this has been attained , also we believe hat these observations show that the preparation is useful, at any rate for "bridging the gap" till the action of dicoumarol (or any other anticoagulant of this group) has fully developed

Summary

A heparin preparation suitable for *intramuscular* injection with prolonged action has been prepared by adding 1 25% carboxymethyl cellulose to heparin solution containing 100 mg per ml We have called the preparation heparin prolongatum

In six normal volunteers we have found that the effect of a single dose of 2 ml of heparin prolongatum is considerable 2 hours after injection, maximum effect is seen 4 hours after injection, and the clotting-time is still clearly prolonged 8 hours after injection

Heparin prolongatum has been used as initial anticoagulant treatment to bridge the gap between the first administration of anticoagulants of the coumarin group and the full effect of these drugs Usually six 8 hourly injections have been given A hundred and thirty-five patients, most of them with coronary occlusion, have been treated Well over eight hundred injections have been given Tenderness, infiltration, and hæmatomas have not been seen

Blood-samples drawn at intervals from patients chosen at random during the treatment with heparin prolongatum indicate that a suitable increase in the clotting-time has been attained

REPORTED side effects of treatment with antibiotics include intestinal disturbances which vary in severity from mild diarrhœa to fatal superinfection by resistant organisms With the increasing use of antibiotics these side-effects are causing widespread anxiety

Their chief cause is thought to be the partial destruction of the natural intestinal flora (Garrod 1955) In the absence of competition and of inhibitory substances such as lactic acid and hydrogen peroxide, produced by the normal flora, antibiotic resistant pathogens can flourish , and the risks of this happening grow greater as resistant strains become more prevalent

Such side effects could perhaps be prevented if, during antibiotic therapy, saprophytic organisms were introduced into the bowel in sufficient numbers to become established Since the beginning of the century this type of therapy has been suggested for a variety of conditions but has fallen into disrepute for a number of reasons

(1) It is essential to provide an organism such as *Lactobacillus acidophilus* which is a normal inhabitant of the intestine and can therefore be established Organisms of doubtful pathogenicity, and species of lactobacilli such as *L bulgaricus* and *L casei* which cannot establish in the gut, have been used because of their less exacting growth requirements

(2) Owing to faulty classification, cultures have been used which were not in fact *L acidophilus*

(3) The viability of liquid cultures declines rapidly, and they usually contain mainly dead or inactive material when used

(4) The growth requirements of *L acidophilus* are complex They are satisfied under normal intestinal conditions, but when various other organisms are destroyed during antibiotic therapy certain factors are lost These must therefore be added at the same time as the culture

(5) It is also of course essential that the strains of *L acidophilus* used be made resistant to the antibiotics if they are to survive during therapy

'Enpac' *L acidophilus* preparation has been developed to meet these requirements It is a culture of strains of *L acidophilus* together with complete growth factors and nutrilites, which has been dried in a manner preserving full viability

The richest sources of these nutrilites and growth factors were found to be unprocessed tomato, autolysates of certain yeasts, and some of the bacterial degradation products of casein For the preparation of the base only crude extracts and concentrates of these materials were used, in view of the labile nature of some of the factors These were blended with full cream milk to which dextrose was added

The lactobacillus used was a human intestinal strain made resistant to penicillin, streptomycin, chloramphenicol, neomycin, chlortetracycline, oxytetracycline, tetracycline, and erythromycin

We have investigated the bacteriological effects of this preparation on the intestinal flora of patients receiving an oral antibiotic

Methods

The 66 patients studied were mainly between the ages of 1 and 13 years, and all received tetracycline 10 mg per kg body weight daily for five days No other antibiotic was used Alternate patients were given 3 g of enpac four times a day, in the intervals between anti-

* Staphylococci were not isolated from the samples which contained lactobacilli

biotic doses, during administration of the antibiotic, and for four days afterwards

Materials

Fæcal specimens were examined (1) before treatment, (2) at the beginning and (3) at the end of antibiotic treatment, (4) at the end of enpac administration, and (5) a week later The fourth and fifth specimens were not always obtained since some patients had already left hospital

Bacteriological Examinations

Each specimen was diluted in saline and counted by the technique of Miles, Misra, and Irwin (1938) on the following media

(1) Beerwort agar for yeasts,
(2) MacConkey s agar for coliforms,
(3) Ludlam s agar (Ludlam 1949) for staphylococci,
(4) Reinforced clostridial medium (R C M) (Hirsch and Grinsted 1954) for enterococci and lactobacilli
(5) R C M plus tetracycline for resistant lactobacilli

A preliminary bacteriological examination of some specimens made it possible to select the dilutions to be counted on the various media The beerwort agar was incubated at room-temperature for five days, the remaining media at 37°C for three days Only the two R C M media were incubated anaerobically The colonies were identified by the catalase test and microscopic examination of Gram-stained films No attempt was made to identify the actual species of each organism, but the coagulase test was used to identify pathogenic strains of staphylococci

Clinical Considerations

The choice of clinical case to be used in this experiment was limited by certain factors Each patient had to suffer from a disease for which tetracycline is a reasonable treatment, but enteric disease had to be excluded as it might complicate interpretation of results, and a simple, reasonably mild, easily treated disease had to be chosen to eliminate as far as possible fallacies associated with severity or diversity of disease Furthermore, the timing, collection, and quick transmission of stool samples proved difficult for the nurses, and arrangements could be entrusted to only one ward of 36 beds

Hence, the series was limited to children suffering from respiratory streptococcal infections and scarlet fever In every case the streptococcal disease cleared up uneventfully The antibiotic caused no evident bowel or other side effects in either the test or the control series The acidophilus preparation was taken by the children with relish and caused no symptoms

Bacteriological Results

Staphylococci (see table) —Initially counts of staphylococci exceeding 5000 per g of stool were found in 39% of all cases Soon after the start of treatment, the staphylococcal counts increased in both groups, and 64% yielded staphylococci The count continued to rise in cases receiving tetracycline only, and by the end of treatment there was a large increase in 76% of these In the group treated with enpac, however, the numbers had decreased, and by the end of the antibiotic treatment samples from only 38% had more than 5000 staphylococci per g After a further two or three days of enpac, this number fell to 12 5% Some strains of staphylococci, isolated at the end of treatment in cases receiving the antibiotic only, were tested for their antibiotic sensitivity, all were resistant to the highest concentration used

Lactobacilli (see table) —In 64% of the cases lactobacilli before treatment numbered over 500,000 per g The number fell when the antibiotic was given alone, and by the end of antibiotic treatment lactobacilli could be isolated in only 4 cases, one strain was resistant In the cases receiving enpac there was a rapid build up of resistant lactobacilli after the initial destruction of sensitive strains by the antibiotic Finally, in all but 2 cases, there were counts in the range of 10^6 to 10^8 Specimens were obtained in only 4 cases a week after the end of enpac treatment, and high levels of lactobacilli were maintained in all

Enterococci —Over 500,000 enterococci per g were found in nearly all specimens, initially and throughout both courses of treatment There was a marked increase in numbers during administration of the antibiotic with and without enpac In specimens obtained a week after treatment had finished, the enterococci had returned to the original level

Coliforms —Only half of the initial specimens showed over 500,000 coliforms per g, and this level was not exceeded at any stage in 20% of cases During treatment there appeared to be no definite relation between the numbers present and the administration of antibiotic, this may or may not have been due to inter species differences It was impossible to count coliforms below 500,000 since the enterococci overgrew them This may be one reason why the percentage of samples showing coliforms is lower than might have been expected

Yeasts —A few yeasts were present initially in about 20%, and a few were isolated at the end of antibiotic treatment, in only 1 case, however, were there many

Discussion

The administration of enpac can check the increase of potentially pathogenic staphylococci and reduce these to the pretreatment levels or lower Competition, the production of inhibitory substances, and the effect of lactic acid on intestinal pH, may all be contributory factors to the suppression of these organisms In the group receiving only antibiotic, at the end of treatment 4 patients still had natural lactobacilli in the stools, and it is interesting that staphylococci could not be found in these cases

Rapid establishment of lactobacilli demands a large number of viable cells, but 6 g of a preparation containing 10^9 lactobacilli per g tended to cause loose stools When the dose was decreased to 3 g of the 10^7–10^8 preparation, this fault disappeared It is of interest that enterococci and lactobacilli were the predominant organisms in initial specimens Coliforms were present in smaller numbers and exceeded 500,000 in only 52% of cases The numbers normally present are very variable (Thomson 1955)

The results of the bacteriological examination of pecimens from the group receiving antibiotic only are n close accord with those of Loh and Baker (1955)

The choice of media and dilutions when examining pecimens with such a mixed and varied flora is always ifficult, and in the absence of completely specific elective media some overlapping is inevitable The nedia used in this work were by no means ideal, but eemed the most satisfactory of those available during rial experiments The use of tomato-dextrose agar Briggs 1953) for counting the lactobacilli had to be disontinued, since its content of Tween 80 allowed the drops o spread during incubation and it was impossible to ount the plates R C M was substituted, though it did iot give as good growth of these organisms and required onger incubation

Summary

66 patients receiving oral antibiotic were divided into two groups and one was given a preparation (' Enpac ') incorporating antibiotic-resistant strains of *Lactobacillus* *acidophilus* Fæcal specimens from all cases were examined bacteriologically at intervals before, during, and after treatment

It was found that the staphylococci increased in both groups at the beginning of antibiotic therapy Staphylococci continued to increase in the patients taking the antibiotic alone, but in those taking enpac there was a pronounced drop in numbers following the initial rise Simultaneously, in this latter group the lactobacilli were rapidly established and continued to multiply This followed the elimination of the normally non-resistant lactobacilli by the antibiotic during the early days of treatment

The 'Enpac' and other material for this work was provided by Messrs Aplin & Barrett, Yeovil

BIOCHEMIST

GENERAL HOSPITAL, BIRMINGHAM

In temperate climates a deficiency of cyanocobalamin (vitamin B_{12}) is found in pernicious anæmia , idiopathic steatorrhœa , strictures, blind loops and anastomoses of the small bowel , and malnutrition Since this deficiency may cause optic atrophy, mental changes, glossitis and subacute combined degeneration of the cord without significant change in the hæmatopoietic system the only reliable method of detecting it is to demonstrate a low serum-cyanocobalamin level by microbiological assay Victor and Lear (1956) emphasise the need of such assays in clarifying certain neurological diagnoses

We describe here a method which is suitable for routine use , report results obtained in certain gastro intestinal disorders some of which we feel are of therapeutic importance , and indicate the need for such determinations

Methods and Material

The level of cyanocobalamin in body-fluids can be determined by microbiological assay using *Euglena gracilis* (Hutner et al 1949), *Lactobacillus leichmannii* (Thompson et al. 1950), or *Ochromonas sp* (Hamilton et al 1952) The *E gracilis* technique, though probably the most sensitive, requires special apparatus and skill and is unsuitable for routine use. Ochromonas though extremely specific, does not appear to be sufficiently sensitive

The method we have adopted is essentially that described by Thompson et al (1950) modified by using the pH change instead of turbidity to measure growth We also emphasise the importance of washing the test organism carefully before transfer to the assay medium, to obviate the carry-over of small amounts of cyanocobalamin which would give inaccurate and high readings This point was also made by Spray (1955)

All the media are obtainable in this country in the dehydrated state from Difco Laboratories through Baird & Tatlock London Ltd They are bacto micro inoculum broth, bacto micro assay culture agar, and bacto B_{12} assay medium *U.S P* (' Difco Certified ')

The organism used is the *L leichmannii* (National Collection of Industrial Bacteria 7854) This is maintained on micro-assay culture agar and subcultured fortnightly

Before an assay a subculture is made into micro inoculum broth and incubated for twenty-four hours at 37°C The growth is centrifuged and washed thrice with single strength B_{12} assay medium and then resuspended in 1 0 ml of the medium 0 1 ml. of the latter is added to a further 10 ml. of the medium and used for the inoculum

Test Solution —About 20 ml of blood is allowed to clot in a sterile universal container The serum is pipetted off as soon as it reaches the laboratory and placed in screw capped sterile containers, which may be stored in the deep freeze refrigerator at −10°C if desired (In this laboratory all assays are performed within a few days of receiving the specimen, and these are kept frozen in an ordinary household refrigerator) An equal quantity of acetate buffer pH 4 6 and 20 ml of distilled water is added to 5 ml. of serum in a boiling-tube, giving a 1 6 dilution of serum at pH 5 1 After thorough mixing a tight-fitting rubber bung with a glass outlet is inserted, and the tube is placed in a water-bath at 100°C for 30 minutes The tube is then cooled and centrifuged. 9 ml of the supernatant fluid is taken and its pH is adjusted to 6 9 with N sodium hydroxide , 6 ml of distilled water is added to give a final total volume of 15 ml , giving a serum dilution of 1 10 For the assay amounts of 2, 3, 4, and 5 ml. of this solution are added to 6 in × $^5/_{8}$ in. tubes and made up to 5 ml. by adding amounts of 3, 2, 1 and 0 ml of distilled water to each tube respectively

Standard Solution —Solution A a stock solution of 0 02 g of cyanocobalamin per 100 ml is made up in sterile buffer 0 62 *M* Na_2HPO_4/KH_2PO_4 pH 6 8 Solution B 0 25 ml of solution A is added to 500 ml of buffer=0 1 µg per ml A drop of toluene is added, and the solution is stored in the dark at 4°C Solution C for the standard solution 1 ml of solution B is made up to 500 ml with distilled water The standard curve is prepared as follows

	Solution C (ml)	*Amount of distilled H_2O to each tube*	*Final concentration of cyanocobalamin (mµg per tube)*
Tube no 1	0	5 000	0
2	0 125	4 875	0 025
3	0 25	4 750	0 050
4	0 375	4 625	0 075
5	0 5	4 500	0 100
6	0 625	4 375	0 125
7	0 75	4 250	0 150

Assay —To both standard and test solutions 5 ml of rehydrated bacto B_{12} assay medium is added so that all the tubes have a final volume of 10 ml All the tubes are sterilised by steam autoclave for three minutes at 15 lb pressure (121°C) Each tube is cooled and inoculated with 1 drop of the prepared inoculum The tubes are incubated for seventy two hours at 37°C, and the production of acid is measured with a pH meter (Pye no 11066) The highest dilution falling on the lowest part of the curve (fig 1) is taken as the reading and the result (which is the total activity of cyanocobalamin) calculated from this is expressed in µµg per ml.

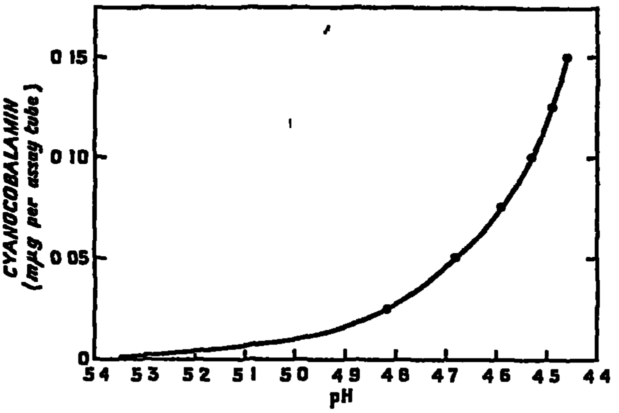

Fig 1—A standard curve of growth

Clinical Subjects—The 43 healthy people used for this investigation were medical students and hospital personnel aged 20–50, two-thirds of them being aged 20–25 The 90 hospital patients used as controls were selected at random, except that patients receiving antibiotic therapy and patients with leukæmia were excluded The diagnosis of cirrhosis of the liver was confirmed by either biopsy or necropsy Most of the 78 patients with idiopathic steatorrhœa and of the 43 with regional ileitis were outpatients attending the nutritional and intestinal follow-up clinic at intervals of three, six, and twelve months and seen during the past twelve months

Results

Mean difference expressed as a percentage of the mean in 34 duplicate observations was 2 97%—S D 2 95, range 0–9 5%

The results of duplicate assays of a pooled serum estimated weekly over fourteen weeks gave a mean of 171 μμg per ml, S D 9 2, range 162–192

In table I our results in healthy people and hospital patients used as controls are given and compared with those reported by other workers and in patients with pernicious anæmia in relapse From these figures we have adopted a normal range of 100–450 μμg per ml of serum

Table II gives the serum cyanocobalamin levels in idiopathic steatorrhœa, regional ileitis, cirrhosis of the liver, ulcerative colitis, and enterocolitis In 22 of 78 patients with idiopathic steatorrhœa the serum-cyanocobalamin levels were below 100 μμg per ml, and in 14 others a deficiency of cyanocobalamin was diagnosed from their hæmatological response to cyanocobalamin therapy In 4 cases it was impossible to know if a deficiency had ever existed, because treatment with cyanocobalamin had not caused any appreciable hæmatological or neurological improvement

Of the 43 patients with regional ileitis 23 had abnormally low serum cyanocobalamin levels and 3 others were being treated with cyanocobalamin for previously diagnosed megaloblastic anæmia Most of these patients and of those with steatorrhœa had no hæmatological manifestations, but some had mild macrocytic anæmia

The serum cyanocobalamin levels in idiopathic steatorrhœa and in regional ileitis contrast with the normal levels found in enterocolitis and in ulcerative colitis and, even more strikingly with the levels in cirrhosis of the liver, where the range was 280–1250 (mean 577) μμg per ml (S D 229) These levels were significantly higher than those found in the healthy people and in the hospital patients used as controls

A more detailed comparison of these groups is made in fig 2

Discussion

All the patients with untreated pernicious anæmia had serum cyanocobalamin levels below 100 μμg per ml, and the lowest level in the healthy controls was 105 μμg per ml We finally adopted 100 μμg per ml as the lowe normal value In the hospital controls 2 patients had values below this 85 and 95 μμg per ml Both had peptic ulcers, one having been admitted after a hæma temesis, and the other having been on a strict diet for many years

As the highest normal value we adopted 450 μμg per ml 3 healthy people had levels above this 475, 500, and 670 μμg per ml The 3rd was an African Of the hospital controls, 1 patient with congestive cardiac failure and hepatomegaly had a serum cyanocobalamin level above 450 μμg per ml, the result of a single assay being 625 μμg per ml Thus 96% of the healthy and the hospital controls had normal levels (100–450 μμg per ml)

Girdwood (1954) included in his controls 3 patients who could have had a deficiency of cyanocobalamin 2 possibly had pernicious anæmia, and 1 had chronic hypochromic anæmia with a gastro enterostomy If these 3 patients are excluded, Girdwood's lower limit of normal was 130 μμg per ml, which level he subsequently adopted (Girdwood 1956)

Unglaub et al (1954) found that 75 μμg per ml was their lower limit Such variations may result from individual differences in assay technique

TABLE II—SERUM CYANOCOBALAMIN LEVELS IN GASTRO-INTESTINAL DISORDERS

Disorder	Serum cyanocobalamin level (µµg per ml)			Previous response to cyanocobalamin therapy	
	< 100	100–450	>450	Positive	Negative
Idiopathic steatorrhœa	22	35	3	14	4
Regional ileitis	23	17	0	3	0
Cirrhosis	0	7	13	0	0
Enterocolitis	0	11	1*	0	0
Ulcerative colitis	0	9	0	0	0

* This patient had associated cirrhosis of the liver

Spray (1955), using traces of cyanide in preparing the extracts of serum, found a normal range of 150–860 µµg with *L leichmannii*

Lear et al (1954) obtained higher values, and Mollin and Ross (1952) obtained results similar to ours Both these groups of workers used *E gracilis* Only in patients aged more than 70 with miscellaneous diseases did Mollin and Ross report results below their normal range of 100 µµg per ml

In 18 patients aged more than 70, most of them with senile vascular disease, we found a mean of 245 (range 90–625) µµg per ml (S D 112 2) None of the patients with pernicious anæmia had levels above 100 µµg per ml

Girdwood (1954) found levels up to 200 µµg per ml

Nieweg et al (1954), using whole blood, found an upper limit of 175 µµg per ml in 6 cases of pernicious anæmia

Unglaub et al (1954) found a range of 10–75 µµg per ml in serum, and Spray (1955) reported 16 of 17 cases of pernicious anæmia in relapse with levels below 100 µµg per ml

Mollin and Ross (1952) and Lear at al (1954), working with *E gracilis*, had ranges of 16–105 µµg per ml and 0–85 µµg per ml respectively

Our findings are in keeping with those of other workers, and we feel justified in regarding levels below 100 µµg per ml as evidence of a deficiency of cyanocobalamin

Our results in patients with cirrhosis of the liver confirmed those of other workers

Lear et al (1954) found that of 29 patients with cirrhosis 5 had abnormally high serum cyanocobalamin levels, and Jones and Mills (1956) found similar values

Baker et al (1956) found in addition a decreased urinary excretion of cyanocobalamin in patients with hepatic disorders after an injection of 50 µg

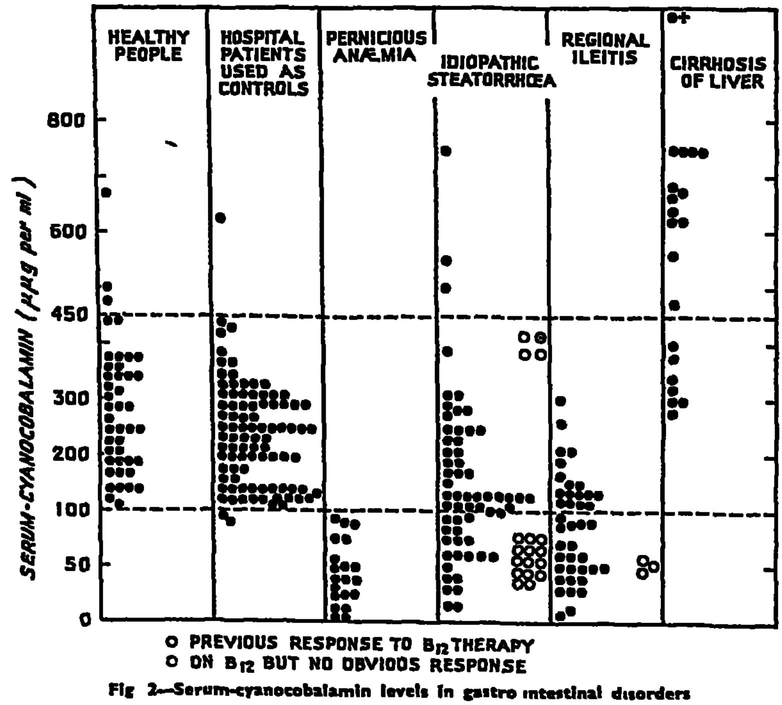

Fig 2—Serum-cyanocobalamin levels in gastro intestinal disorders

Rachmilewitz et al (1956) found that the cyanocobalamin-binding capacity of the serum of patients with cirrhosis and of patients with infectious hepatitis was increased but they could not find any correlation between raised serum cyanocobalamin levels and the amount of serum globulin, which is said to be the cyanocobalamin-binding protein (Pitney et al 1954) At present there is no adequate explanation for these observations

A deficiency of cyanocobalamin in idiopathic steatorrhœa has previously been recognised by the hæmatological response to therapy, but the incidence (36 of 78) in our group was somewhat surprising

Girdwood (1956) found only 1 patient with a low serum-cyanocobalamin level among 29 patients whom he investigated because of intestinal malabsorption of the sprue type

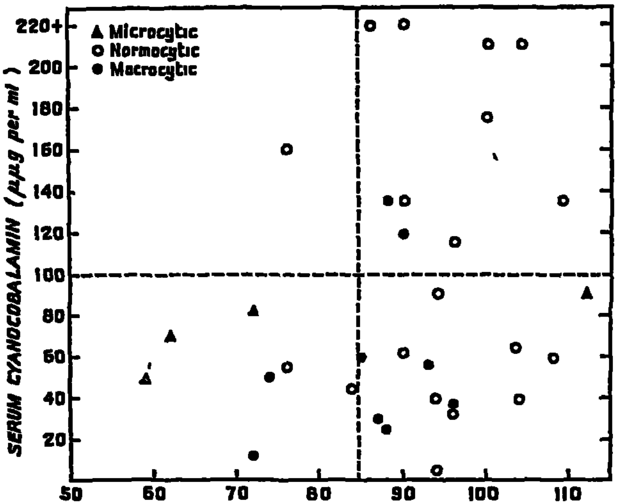

Fig 3—Hæmatological picture compared with serum cyanocobalamin level in regional ileitis

Callender and Evans (1955) found, in 7 of 13 patients with steatorrhœa, defective absorption of cyanocobalamin comparable to that found in pernicious anæmia

A large proportion of our patients had some hæmatological abnormality, shown by the number already being treated with cyanocobalamin Others, however, developed a deficiency of cyanocobalamin although their blood counts were relatively normal or they were already well controlled with folic acid

Megaloblastic anæmia has been reported in patients with regional ileitis and in patients with small-bowel lesions (Barker and Hummel 1939, Jensenius 1945, Cameron et al 1949, Watson and Witts 1952, Thompson and Ungley 1955, Halsted et al 1956), and in most of them a deficiency of cyanocobalamin was shown by, or seemed probable from, their response to cyanocobalamin Poor absorption of radioactive cyanocobalamin in regional ileitis was found by Halsted et al (1956) in 3 patients, by McIntyre et al (1956), and by us in 2 patients Nevertheless, the high incidence of low serum cyanocobalamin levels found by us in regional ileitis was unexpected Most of these patients had free hydrochloric acid in their stomachs and but little anæmia (fig 3), but some had loss of weight, energy, and concentration, and irritability and other personality changes, including occasional psychoses The fact that both in the patients with idiopathic steatorrhœa and in the patients with regional ileitis these symptoms cleared up under treatment with cyanocobalamin leads us to suppose that a low serum cyanocobalamin level indicates an absolute deficiency of cyanocobalamin in the body

Summary

A method suitable for a routine laboratory is described for determining the serum-cyanocobalamin level

The normal range of values of the serum-cyanocobalamin level was taken to be 100–450 μμg per ml

Serum cyanocobalamin levels above 450 μμg per ml were found in 13 of 20 patients with cirrhosis of the liver

Serum-cyanocobalamin levels below 100 μμg per ml or therapeutic evidence of deficiency were found in 36 of 78 patients with idiopathic steatorrhœa and in 26 of 43 patients with regional ileitis

We are glad to acknowledge financial support from the medical research endowment fund of the United Birmingham Hospitals for technical assistance

LESIONS OF THE HYPOTHALAMIC REGION AND SERUM-PROTEIN LEVELS

PETER LOMAX
M B Manc
SENIOR HOUSE OFFICER, DEPARTMENT OF NEUROSURGERY, MANCHESTER ROYAL INFIRMARY

IN view of the importance of the brain in regulating bodily functions it is surprising that focal damage to the brain has not been more frequently associated with metabolic changes It is well known that the hypothalamus is either directly or indirectly concerned with regulating the metabolism of carbohydrate and fat, water balance, and vasomotor activity, and that lesions in the hypothalamic region can disturb these functions No report of disturbances of protein metabolism in association with focal lesions of the brain seems to have been published

The qualitative and quantitative alterations in the serum-proteins have been studied in a wide range of diseases (Gutman 1948)

Roboz et al (1955) found changes in the serum protein levels both with benign and with malignant neoplasms of the central nervous system but did not discover any correlation between the site of the lesion and the disordered pattern Magraf (1953), Shetlar et al (1950), and other workers found abnormal protein levels with malignant but not with benign tumours in other parts of the body

Mider et al (1950) was of the opinion that the protein change was independent of the site of the tumour, but only two of his patients had intracranial growths

I report here alterations in the serum-protein pattern in certain neurosurgical conditions and suggest that lesions affecting certain not yet accurately localised basal regions of the brain are responsible for these changes

Attention was first drawn to the serum protein levels in connection with checking the adequacy of nutrition of comatose patients, especially those with head injuries These patients were given, through a Ryle's tube, a diet of about 2000 calories daily containing 90–100 g of first class protein

Methods

Estimation of Serum-protein Levels

The serum-protein levels were estimated in the department of chemical pathology at Manchester Royal Infirmary The biuret method, as described in the American Association of Clinical Chemists' publication, Standard Methods in Clinical Chemistry, vol I, was used With this technique standard normal values are as follows

Serum albumin 3 8–4 6 g per 100 ml
Serum globulin 2 2–3 5 g per 100 ml

Feeding of Unconscious Patients

All the patients who were unconscious or unable to swallow were fed by Ryle's tube with a feed based on 'Complan,' Glaxo, which was modified because the protein content of 140 g in a 2000 calorie daily feed seemed to be too high

The feeds were prepared daily in the dietetic department and kept in the ward refrigerators Immediately after admission frequent feeds of small volume were given, and, as the patient improved, the volume and the time between each feed were increased From 3½ to 4½ pints of the feed was given daily, the total volume of fluid being made up to 5 pints with water, usually given in a small amount after each feed to clear the Ryle's tube

The mixture consisted of water 5 pints, complan 12 oz, lactose 8 oz, sodium chloride 5 g, and vitamin C 50 mg

Illustrative Case-reports

CASE 1 —A man, aged 42, was involved in a road accident on Oct 9, 1955 He was admitted unconscious with no history of a lucid interval Radiography revealed extensive fractures of the right temporofrontal region Shortly after admission both pupils became dilated and fixed, respiration became irregular, and the blood pressure began to rise At operation a large left sided hæmatoma was removed and a right temporo parietal bone flap was taken out to decompress the swollen lacerated brain After this his respirations became regular and blood pressure fell to 80/55 mm Hg Next day his temperature rose to 104°F, and for the following eight days ice packs to the skin and chlorpromazine were used to keep his temperature down to normal On Oct 14, 1955, tracheostomy was done, and he remained in an oxygen tent until Nov 10, 1955, when his respirations were satisfactory and he was beginning to take fluids by mouth He slowly improved and by Feb 27, 1956, could reply to questions and was taking a normal diet There was, however, severe mental deterioration, his behaviour was primitive and childlike, with periods of violence He was transferred to a mental hospital on May 2, 1956

Serum protein levels were as follows

Date	*Albumin (g per 100 ml)*	*Globulin (g per 100 ml)*
Oct 22 1955	2 4	5 1
Nov 2	1 9	5 2
8 ,	2 2	5 0
„ 16, „	2 7	4 7
28	3 0	4 7
Jan 2, 1956	4 0	3 7
Feb 7	4 0	3 1

On Nov 2, 1955, electrophoresis showed a low serum-albumin level with increased globulin, especially the gamma fraction

Case 2 —A woman, aged 48, was admitted to hospital after a car crash on Oct 29, 1955 She had a laceration over her left frontal region, was deeply unconscious, responding only slightly to painful stimuli and had a dilated and fixed right pupil Four days later, still unconscious, she was transferred to Manchester Royal Infirmary There was no localising sign other than the unreactive pupil, both plantar responses were extensor, and radiography of the skull revealed no evidence of a fracture Bilateral burr holes revealed the brain to be under normal tension with no evidence of either extradural or subdural hæmatoma The patient's general condition slowly deteriorated, pulmonary congestion developed, and she died on Nov 7, 1955

Serum protein levels were as follows

Date	*Albumin* (*g per 100 ml*)	*Globulin* (*g per 100 ml*)
Nov 4 1955	3 1	2 6
7, ,,	2 4	2 7

Necropsy was ordered by the coroner of the area in which the accident happened and was not done at this hospital We could not procure a detailed report of the findings No significant amount of intracranial clot was said to have been present, and there was " no evidence of a pressure cone at the tentorium " Death was regarded as being immediately caused by the pulmonary condition

Case 3 —A man, aged 69, was knocked down by a car on Jan 14 1956, and admitted to hospital in deep coma His pupils were equal and reactive, and there were no localising neurological signs He had a laceration over the occiput, but no fracture of the skull was seen on radiography He was still unconscious on Jan 17, 1956, when his left limbs showed increased tone over the right, and the left plantar response became extensor Bilateral burr holes revealed a subdural hæmatoma about 2–3 mm deep covering the right parietal and left frontal cortex Lumbar puncture on Jan. 19, 1956 revealed a bloodstained cerebrospinal fluid (C S F) under a pressure of 120 mm Tracheostomy was done on Jan. 24, 1956 The patient made a slow return to consciousness and by Feb 7, 1956, was trying to talk and taking food by mouth By March 3, 1956, he could walk unaided, but there were signs of gross organic dementia, and he was eventually admitted to a mental hospital in May, 1956

Serum protein levels were as follows

Date	*Albumin* (*g per 100 ml*)	*Globulin* (*g per 100 ml*)
Jan 21 1956	3 7	3 3
30	3 2	5 3
Feb 4	2 9	4 6
8	2 8	4 6
22 ,,	3 1	4 3
March 3	3 4	4 0
April 30	3 9	3 7

On Feb 4, 1956, electrophoresis showed low serum albumin and raised serum globulin levels, most evident in the gamma fraction

Comment —It seemed unlikely that these changes could be regarded as nutritional because the patients were all receiving an adequate intake of protein and calories In case 1 there had been evidence of severe damage to the mid-brain the pupillary changes, the respiratory and cardiovascular changes, and the loss of temperature control Thus the possibility arose that lesions of the mid-brain might be responsible for the altered protein levels Accordingly the serum-protein levels of other neurosurgical patients were determined especially those with lesions of the mid brain

Case 4 —A woman aged 43, was admitted to hospital on Dec 14, 1955 Three years previously she had begun to have attacks in which she " had become hazy for a moment " and had visual hallucinations of people she had known previously In 1953 she began to get frequent headaches and associated with these ' spots before the eyes During the twelve months before her admission her vision had gradually deteriorated sometimes almost disappearing and then recovering She also slept more than formerly was becoming increasingly thirsty, and was having more severe headaches

On examination she had bilateral anosmia and severe bilateral papillœdema with venous engorgement and exudates Her visual acuity was J10 right and J12 left Small but definite supraclavicular pads of fat were present Charting of the visual fields showed an enlarged blind spot on each side, her C S F contained 280 mg of protein per 100 ml and air encephalography and 'Myodil' ventriculography showed a filling defect of the anterior end of the third ventricle

Craniotomy on Jan 28, 1956, revealed a greyish-pink tumour involving the chiasma and extending upwards towards the floor of the third ventricle A biopsy specimen was taken and the flap was closed. Histologically the specimen showed dense fibrillar gliosis with spindle shaped nuclei, suggesting a benign tumour of the chiasmal type

Postoperatively the patient's vision improved to J6, J4 (similar improvement had taken place on previous occasions) She was discharged from hospital on Feb 15, 1956, and was seen as an outpatient on April 9, 1956, when her vision showed no change but her optic discs now showed consecutive atrophy Her weight was increasing, she had polydipsia and polyuria, and during the previous few weeks she had been having attacks, lasting a few minutes, in which she felt faint and giddy and became flushed and hot

Serum-protein levels were as follows

Date	*Albumin* (*g per 100 ml*)	*Globulin* (*g per 100 ml*)
Jan 13 1956	2 9	4 5
20 ,,	2 9	2 9
Operation		
Jan 29 ,,	3 7	3 7
Feb 4	3 4	3 4
April 9,	3 3	4 2

On Feb 4, 1956, electrophoresis showed a slight rise in the level of α_2 globulin

Case 5 —A woman aged 52, was first admitted to the neurosurgical unit on Dec 28, 1954, with five years' history of progressive increase in weight, lack of energy, hypersomnia, and failing vision. On Feb 3, 1955, her optic chiasma was explored, and a purplish tumour was seen protruding from behind it A needle introduced into the tumour yielded 0 75 ml of yellow fluid It would have been impossible to obtain a biopsy specimen without dividing the optic nerve, so the flap was closed The patient made an uneventful recovery from the operation, her sight remaining unchanged In March, 1955, she was given a course of radiotherapy.

Readmission —On Sept 29, 1955, she was readmitted to hospital because of rapidly failing vision and increasing drowsiness She was still gaining weight and had severe polyuria On examination she was confused and her speech was slurred Her optic discs were severely atrophied, her blood-pressure was consistently low, and she had slight left-sided pyramidal signs Cortisone improved the blood pressure without altering her general condition The original flap was reopened on Nov 4, 1955 Tumour tissue was seen indenting the right optic nerve and spreading up behind the chiasma A biopsy specimen of this appeared histologically to be a glioma The patient went steadily downhill, lapsed into coma, and died on Dec 1, 1955

At necropsy a carpet of glioma was found growing from the floor of the third ventricle

Serum-protein levels were as follows

Date	*Albumin* (*g per 100 ml*)	*Globulin* (*g per 100 ml*)
Nov 7 1955	2 6	4 3
23	3 3	4 4

On Nov 23, 1955, electrophoresis showed an increase in the gamma globulin

Case 6 —A woman, aged 54, had complained since 1953 of headaches failing memory, and, later, unsteadiness of her limbs and vomiting Air encephalography and air ventriculography revealed an obstruction at the posterior part of the third ventricle and proximal part of the aqueduct (fig 1) and internal hydrocephalus This was regarded as being due to a slowly growing mid brain tumour In June, 1955, a right sided Torkildsen s ventriculo-cisternostomy was done After this she improved considerably and went home at the end of July In October, 1955, her condition suddenly deteriorated and she became unresponsive, mute, and incontinent After admission to hospital, however, she slowly but spontaneously recovered Radiography showed that the lower end of the tube was about 5 cm above the cisterna magna, so the posterior fossa was reopened and the tube replaced in the cistern

Postoperatively the patient rapidly recovered and went home in mid April When she was next seen as an outpatient

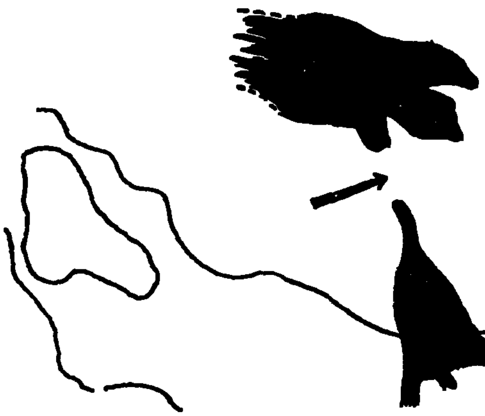

Fig 1—Case 6 composite drawing of air encephalogram and air ventriculogram, showing obstruction of proximal end of aqueduct

in June, her only complaints were of sleepiness and increased weight

Serum protein levels were as follows

Date	*Albumin* (*g per 100 ml*)	*Globulin* (*g per 100 ml*)
Dec 19, 1955	3 2	3 3
,, 30	3 3	3 7
March 14, 1956	2 9	4 0
21 ,,	2 9	3 9
Operation		
June 11, ,,	3 6	3 8

On March 21, 1956, electrophoresis showed a low serum albumin level with a normal globulin pattern

Case 7—A woman, aged 50, was admitted on March 13, 1956, having first noticed failure of vision in 1948 Her sight remained stationary until mid 1955, when it rapidly deteriorated further, the left eye being more affected than the right

On examination there was primary atrophy of both optic discs, and the left eye was blind, but there was some remaining vision in the right nasal field Radiography revealed erosion of the dorsum sellæ, air encephalography showed a midline tumour extending into the third and fourth ventricles (fig 2), and the C S F contained protein 180 mg per 100 ml There was no clinical or biochemical evidence of pituitary failure

Operation—A left frontal osteoplastic flap was turned, and a meningioma was found attached to the orbital roof and extending 1 5 cm in front of the orbital ridge The left optic nerve was bowed forwards over the main mass of the tumour, which lay behind it The meningioma was growing from the dorsum sellæ and raised the floor of the third ventricle, making the risk of attempted removal prohibitive The patient made a good postoperative recovery, but her eyesight remained unchanged She subsequently received a course of radiotherapy

Serum protein levels—On March 16, 1956, the serum albumin level was 2 9 g per 100 ml and serum globulin level 3 4 g per 100 ml

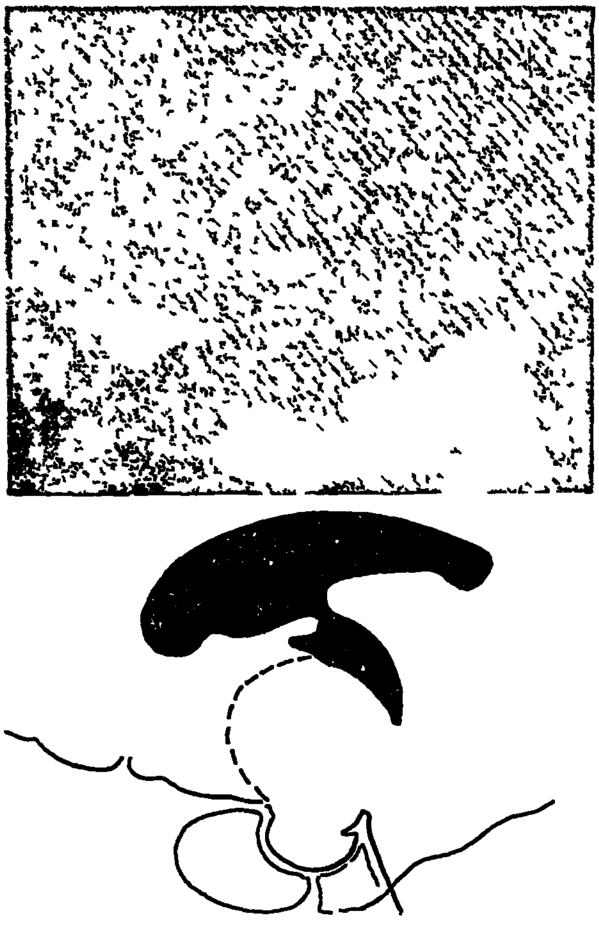

Fig 2—Case 7 air encephalogram and drawing, showing large suprasellar tumour extending into third and fourth ventricles

Controls

During the period of the investigation the serum protein levels of 44 other patients were determined These control patients cannot be regarded as a completely random group, because (1) the aim was to cover a wide variety of lesions, and (2) all patients with suprasellar tumours were investigated In all the following cases the serum albumin and serum-globulin levels were within normal limits

Condition	*No of cases*
Malignant supratentorial glioma	9
Craniopharyngioma	5
Chromophobe adenoma	5
Supratentorial meningioma	4
Acoustic neurinoma	2
Subdural hæmatoma following head injury	4
Extradural hæmatoma following head injuries	3
Subarachnoid hæmorrhage from aneurysm	2
Acromegaly	3
"Pseudotumour"	1
Frontal tuberculoma	1
Cervical prolapsed disc	1
Cord meningioma	1
Brain stem glioma	1
Congenital stricture of iter	1
Brain stem thrombosis	1

Several of these patients were unconscious for periods varying from a few days to several weeks and were fed by the procedure used for head injury patients In these cases the serum-protein levels were estimated at intervals, but no abnormality was found

The patients with tumours arising from the pituitary fossa all showed moderate suprasellar extensions on air encephalography, and in most of them the third ventricle was displaced In none of these patients was there any radiological sign of tumour growth into the third ventricle All the patients with craniopharyngioma and two with chromophobe adenoma presented clinical and biochemical evidence of hypopituitarism, and in all these cases the serum protein levels were estimated before cortisone was administered

Discussion

The various structures and connections of the base of the brain are not yet precisely defined, and rarely are pathological lesions sufficiently circumscribed to allow accurate localisation of the part mainly affected Because of this difficulty of localisation the broad term "hypothalamic region" has been used in the title of this paper

In the seven cases studied there is adequate evidence that this region was primarily involved, and in none of them is there reason to believe that other areas of the brain might be seriously damaged except in case 1, where, however, the bilateral dilated pupils, loss of temperature control, and long period of unconsciousness bore witness to trauma suffered by the brain stem.

It is unlikely that the disorder of protein metabolism in such cases is due to environmental circumstances, because several of the controls had periods of unconsciousness and tube-feeding. Moreover in cases 4, 6, and 7 abnormal serum-protein levels were present while the patients were ambulant and receiving a normal diet. Although there is a relationship between the duration and degree of unconsciousness and the serum-protein levels in cases 1 and 2, it seems reasonable to assume that both are a reflection of the original focal damage to the brain.

That the protein change is not due to the type of tumour seems certain; meningiomas and gliomas in *other areas did not alter the protein pattern.*

It was at first thought that the change might be due to disruption of the hypothalamic-pituitary mechanism, but none of the seven patients provided any clinical or biochemical evidence of pituitary insufficiency, and in patients with severe panhypopituitarism no qualitative alterations in the serum-protein levels were found.

The first change to develop appears to be a fall in the serum-albumin level, and this is closely followed by a rise in the serum-globulin level. With recoverable lesions the serum-albumin level returned to normal before the increased serum-globulin level fell to normal. Where electrophoresis was done no specific change was found in any one fraction. *At all times the total serum-protein* level was normal. In none of the seven patients was there any abnormality in either the serum electrolyte levels or the blood-urea level when the serum-protein levels were estimated.

All but one of the patients were incontinent of urine and fæces during the period in which abnormal serum-protein levels were present. In case 4, however, the nitrogen balance was studied. From Feb. 3 to Feb. 7, 1956, this patient received a diet containing 70–90 g. of protein daily. Urine and fæces were collected, and their nitrogen content was estimated, from Feb. 5 to Feb. 7, 1956. During this time case 4 excreted 3500 ml. of urine containing *17.6 g. of nitrogen and her fæces contained* 19.4 g. of nitrogen. Thus during the test period the intake and output of nitrogen were about equal. Bodansky (1938) found the normal daily total nitrogen output in the urine to be 13.2 g. Thus in case 4 the urinary output of nitrogen was abnormally low, and probably there was incomplete absorption of protein during the test period. In this respect it is interesting to recall the work that has been reported, particularly that of Kabat et al. (1935), showing that stimulation of the lateral nuclei in the hypothalamic region leads to a decrease of gut motility and gastric secretion in laboratory animals.

The mechanism by which these alterations in serum-protein levels take place and the significance of the change are obscure; but determination of the serum-protein levels may be of value in the diagnosis of lesions involving the hypothalamic region and in assessing recovery in certain head injuries before there is any clinical improvement in consciousness.

Summary

Seven cases of lesions involving the hypothalamic region are described.

In all of them the serum-protein levels were changed, the serum albumin level being lowered and the serum globulin level raised.

In 44 control patients the serum-protein levels were normal.

The disturbance of protein metabolism is probably due to a specific cerebral disorder rather than an alteration in the environmental circumstances.

Determination of the serum-protein levels may be of diagnostic and prognostic significance in patients with lesions of the hypothalamic region.

I wish to thank Mr. H. Varley and the Department of Clinical Pathology for estimating the serum-protein levels; the Department of Neuroradiology; the Department of Medical Illustration and Miss D. Davison for the illustrations; and especially the nurses for their untiring efforts over many weeks, particularly in the care of the patients with severe head injuries.

MANAGEMENT OF FRACTURES THROUGH FEMORAL METASTASES

ANTONY F. WALLACE
M.B. Lond., F.R.C.S.

ASSISTANT SURGICAL REGISTRAR,
UNIVERSITY COLLEGE HOSPITAL, LONDON

IT is important to know the prognosis of any disease syndrome as precisely as possible before planning its treatment.

Petit described in 1723 multiple fractures in a woman with carcinoma of the breast. How to treat such fractures is not easily decided. The introduction of intramedullary nailing by Küntscher (1940) suggested the possibility of internal fixation instead of traction or plaster in the treatment of femoral fractures, and since then this or some other surgical technique has been used and reported by numerous workers. Internal fixation in anticipation of a fracture has also been advocated and practised (Griessmann and Schüttemeyer 1947).

Altman (1953) originally described the successful use of trifin nails and of nails and plates to stabilise fractures through deposits in the femoral neck and trochanteric region.

D'Aubigne (1951) described the insertion of an acrylic prosthesis to replace a carcinomatous femoral head.

Ehrenhaft and Tidrick (1949), Rossi (1953), Altman (1953), and Devas et al. (1956) have discussed the management of pathological fractures through metastases and have described their own cases.

Bickel and Barber (1951) from the Mayo Clinic and Fitts et al. (1953) have given brief descriptions only of substantial numbers of patients.

All these workers dealt with management or described operations but rarely stated how long the patient survived *operation.*

I review here the cases of all 22 patients treated in University College Hospital between 1943 and 1956 for fractures of the femur through secondary carcinomatous deposits. This analysis seems to show that the treatment of a fracture of the femur at the site of a secondary deposit should be influenced by one fact—i.e., whether the metastasis is solitary or one of several. If it is solitary, the expectation of life is longer, and therefore an attempt probably successful should be made to achieve osseous union. If there are multiple metastases, there is no likelihood of long survival, and the object should be to make the patient comfortable. *Osseous* union, which demands more stringent *treatment,* is unnecessary for this.

The Patients with Fractured Femurs

All were women with carcinoma: in 17 the primary tumour was in the breast, in 4 in the thyroid gland, and

TABLE I—PATIENTS WITH MULTIPLE METASTASES OF MAMMARY CARCINOMA AT TIME OF FEMORAL FRACTURE

Case no	Age at start of history (yr)		Histology of carcinoma	From start of history to fracture (mos)		Site of fracture	Survival after fracture (mos)	Time for fracture to unite (mos)	Special treatment of fracture	Year of fracture
1	38	Pre menopausal	Anaplastic duct	40		Upper $^1/_3$	2	Ununited		1953
2	38		Spheroidal cell	21		Upper $^1/_3$	6	,,	Androgens	1950
3	40		Scirrhous adenocarcinoma	36	Both femurs	Middle $^1/_3$	3	,,		1951
				38		Middle $^1/_3$	1	,,		1951
4	40			32		Upper $^1/_3$	1		Androgens	1948
5	41		Mucoid	34		Middle $^1/_3$	3			1951
6	44			32		Middle $^1/_3$	1			1955
7	45 ?			25		Lower $^1/_3$	4	,,	Radiotherapy	1947
8	58	Post menopausal	Small duct	5		Neck	10	,,	Androgens	1955
9	59		Anaplastic small duct	15		Middle $^1/_3$	5		Radiotherapy	1956
						Lower $^1/_3$				
10	66			83–94		Lower $^1/_3$	4–15	,,	Amputation	1951

Case 10 lived ninety eight months in all, but the month of the year in which her fracture occurred is unknown

TABLE II—PATIENTS WITH SINGLE METASTASIS OF MAMMARY CARCINOMA AT TIME OF FEMORAL FRACTURE

Case no	Age at start of history (yr)		Histology of carcinoma	From start of history to fracture (mos)	Site of fracture	Survival after fracture (mos)	Time for fracture to unite (mos)	Special treatment of fracture	Year of fracture
11	37	Pre menopausal	Scirrhous adenocarcinoma	48	Upper $^1/_3$	29	?	Radiotherapy	1948
12	44		Anaplastic small duct	21	Neck	17	Ununited	Radiotherapy androgens	1955
13	63	Post menopausal	Undifferentiated	18	Upper $^2/_3$	4 +	? United in 4	Intramedullary nail, radiotherapy, androgens	1956
14	63		Duct	21	Neck	6	Partially united in 6	Radiotherapy	1951
15	64			23	Upper $^1/_3$	12 +	Ununited	Radiotherapy nail and plate	1955
16	67			47	Upper $^1/_3$	16 +	United in 4	Intramedullary nail, radiotherapy	1955
17	67			33	Neck	10	United in 4	Radiotherapy	1953

"Partially united" in case 14 is a quotation from a necropsy report +, Still alive on last day of 1956

in 1 in a bronchus (The principal primary site of the carcinoma in previously published cases was the breast)

Tables I and II contain details of the eighteen fractured femurs in the 17 patients whose primary tumour was in the breast The youngest woman in each group is put first and the others follow in order of age recorded at the time of the first symptom caused by their primary carcinoma The age distribution in the two groups is similar The same histological types of carcinoma occur in both Details of external splinting in a Thomas's splint, plaster spica, or walking calliper have been omitted from the treatment column

One criterion alone was adopted in separating the two groups the question was asked, "At the time the fracture occurred was there clinical or radiological evidence of other bloodborne metastases ?"

The femoral fractures of the women in table I who at the time showed definite evidence of other metastases were all ununited at death, and none of the women lived longer than ten months after her fracture

In table II are listed the women who showed no evidence of other bloodborne metastases, they lived much longer after their fracture—up to two and a half years They were confined to bed initially In the patients in whom the fracture did unite it did so in about four months, judged on clinical examination and on radiological evidence that osseous union was taking place

Living with a leg stabilised by an internal splint of metal is a vast improvement on life with a Thomas's splint or a plaster spica Radiotherapy can be given as soon as the surgical incision has healed, and sex hormones may be prescribed in cases of mammary and prostatic carcinoma With internal splinting pain is relieved, nursing and radiotherapy are facilitated, and some patients learn to get about on crutches two weeks after their operation

Surgery is contra indicated when a large mass of tumour infiltrates the soft tissues of the thigh at the site of the fracture I have not been able to find any published case in which death was attributable to an operation on a femur with a fracture at the site of a metastasis, either from fat embolism or any other cause

Though early mobilisation is desirable, it delays union of the fracture and may prevent it When the expectation of life is short, this is of little consequence

Conclusion

The history of these 17 patients suggests that the correct surgical management of a woman with a fracture of her femur through a metastasis from a carcinoma of the breast depends on whether or not there is clinical or radiological evidence of other bloodborne metastases If such metastases are present, she will probably die within six months, and her fracture will remain ununited even with complete rest in bed If no other bloodborne metastases are found, it is justifiable and correct to confine the patient to bed, making every effort to secure union of the fracture, because there is a good chance that it will unite in about four months, and the patient may live for two and a half years

Although the prognosis of the patients in the two groups differs considerably, they may all be considered for treatment by operative stabilisation of their fracture with an intramedullary nail for a shaft fracture, and a trifin nail, or a nail and plate, for fractures at the upper end of the femur

I wish to thank the consultant staff at University College Hospital, London, for permission to publish details of the patients under their care For advice and constructive criticism freely given during the preparation of this paper, I am indebted to Dr Gwen Hilton, who has cared for all the patients in this series, and to Mr C W Flemming, who has treated many of the patients and who performed all the operations on the femurs

MIXED ADRENOGENITAL-CUSHING SYNDROME FOLLOWING THYROIDECTOMY

P G BEVAN
M B Birm, F R C S
LECTURER IN SURGERY

K R THORNTON
B Sc, M B Leeds
LECTURER IN PATHOLOGY

IN THE UNIVERSITY OF BIRMINGHAM

THE relationship of the adrenal cortex to the thyroid has been extensively investigated, and clinical and experimental observations have shown that corticotrophin and cortisone, or other adrenal cortical steroids, can modify the activity of the thyroid gland The nature of this adrenal thyroid relationship has been investigated in rats and guineapigs with reference to the production of exophthalmos (Aterman 1952, 1954, Aterman and Greenberg 1954), organ weights, growth, and food utilisation (Greenberg and Aterman 1955), and the prevention of hepatic necrosis (K Aterman, personal communication), and it has been shown that the thyroid and adrenal cortical secretions have mutually antagonistic actions In particular, thyrotoxicosis can suppress the effects of hypersecretion of the adrenal cortex or cortisone administration, and thyroidectomy can cause the appearance of hitherto suppressed symptoms of cortical hyperactivity

In the case described here the appearance of a mixed Cushing-adrenogenital syndrome closely followed thyroidectomy in a patient with an adrenal carcinoma which had shown no characteristic hormonal effects

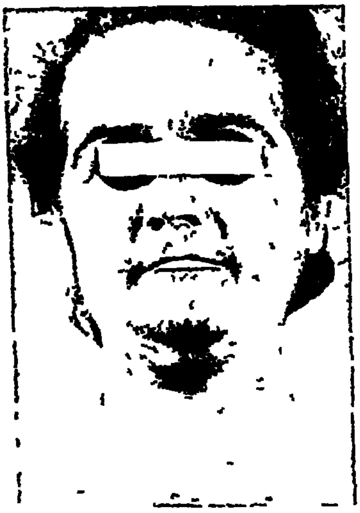

Fig 1—Patient showing hirsuties, acne, moon face, and thyroidectomy scar

Case-report

A married woman, aged 35 (fig 1), with three children, presented in November, 1954, with slightly irregular menstrual periods, dyspnœa and choking, sweating, agitation, and recent enlargement of a goitre which had been present for twelve years She had a diffuse goitre, tremor, moist palms, tachycardia, and blood pressure 160/80 mm Hg, but no exophthalmos Mild thyrotoxicosis was diagnosed, and subtotal thyroidectomy was done at another hospital on Feb 24, 1955 Her thyroid gland had large colloid filled acini lined by flattened epithelium, resembling those found in simple colloid goitre (fig 2)

The patient developed amenorrhœa in March and swelling of the ankles in May In June she noticed increasing growth of hair on her upper lip and chin, increased deposition of fat on her abdomen, and the appearance of striæ on her legs and abdomen like the striæ which appeared after her pregnancies She was advised by her doctor to take less salt and on this regime her ankle swelling subsided for two weeks She developed pain in the small of her back, later radiating down the inside of her thighs to her knees She was admitted to hospital on Oct 5, 1955

Examination

She was well nourished, with hirsuties and fullness of the face, and acne of the face and chest Her skin and hair were coarse, she had very slight pitting œdema of her ankles and striæ on her thighs and abdomen resembling striæ gravidarum A large hard mass in the right lumbar region moved on respiration and was not tender or fluctuant Her clitoris was slightly enlarged and her pubic hair of female distribution Her blood pressure was 135/95 mm Hg

Investigations

Serum sodium 136 m eq per litre, serum potassium 5 6 m eq per litre, serum chloride 105 m eq per litre, serum alkaline phosphatase 7 4 units per 100 ml (These values are within the range accepted as normal) White cells 8600 per c mm (no eosinophils seen) Urinary excretion of 17-ketosteroids 52 mg in 24 hr (normal range in Dr A C Crooke's laboratories is 12 ± 6 mg in 24 hr) Intravenous pyelography showed that the right kidney was displaced downwards and rotated by a large vague mass lying above it There was no albuminuria

Diagnosis

In view of the hardness and size of the mass in the loin, the pain in the back and thighs, and the ankle œdema it was decided that a carcinoma of the right adrenal gland was producing a mixed Cushing adrenogenital syndrome

Further Course

On the fifth night after admission, before an operation could be done, the patient suddenly collapsed She became shocked, with pallor, sweating, a small pulse (rate 100), and systolic blood-pressure 80 mm Hg There was no abdominal rigidity or tenderness, but there was gross œdema of the legs and thighs

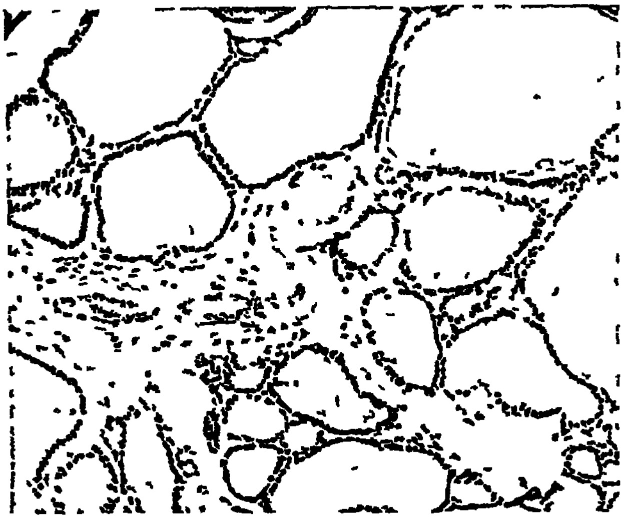

Fig 2—Thyroid gland, showing large colloid filled acini with flattened epithelium

Emergency investigations showed serum sodium 143 m eq per litre, serum potassium slightly raised (6 0 m eq per litre), serum chloride 104 m eq per litre, blood urea 38 mg per 100 ml, some hæmoconcentration, urine sp gr 1 018, albuminuria +++ In spite of the exhibition of intramuscular hydrocortisone 100 mg her condition rapidly deteriorated and she died

From the clinical point of view this severe spontaneous collapse was thought to indicate final adrenal failure due to hæmorrhage or metastasis in the remaining functional adrenal tissue

Necropsy Findings

The body was moderately obese (weight 74 1 kg, length 5 ft 7 in) The extremities were cyanotic, and there was œdema of the legs Hirsuties, facial acne, striæ on abdomen and legs, and clitoral enlargement were confirmed There were two small xanthomas at the inner angle of the left eye The breasts were well developed

The abdominal cavity contained 800 ml of straw coloured fluid There was a mass in the right upper quadrant, attached to the upper pole of the right kidney, measuring 22 × 15 × 15 cm It was encapsulated, and there were many vessels coursing over its surface Its cut surface was soft and brownish yellow, with areas of old and recent hæmorrhage The tumour had invaded the suprarenal veins and, through these, the inferior vena cava immediately below its intrahepatic portion The last centimetre of the hepatic veins and the intrahepatic vena cava were blocked by a cord of tumour ascending and terminating in a globular mass, 2 5 × 2 5 × 4 cm, in the right atrium

Tumour embolus plugged a secondary branch of the pulmonary artery, distal to this the lung had a pale infarction Throughout the lungs were scattered secondary deposits of the neoplasm up to 0 5 cm in diameter There was a massive intrabronchial hæmorrhage, the source of which was presumed to be the secondary growth

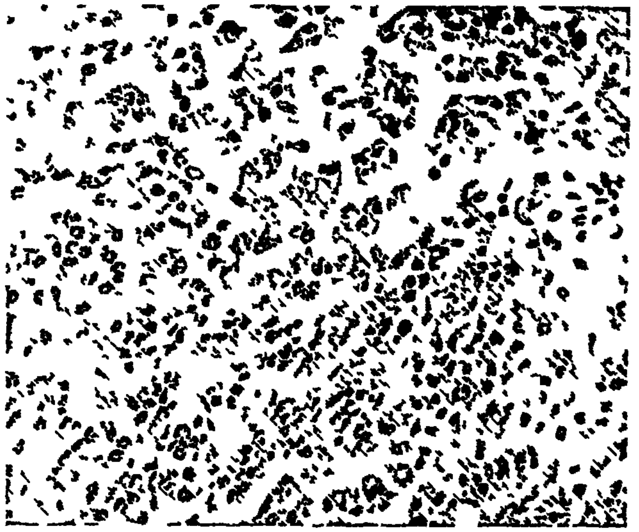

Fig 3—Adrenal carcinoma

The left adrenal gland was much atrophied (4 g) The ovaries were atrophied, there were no corpora hæmorrhagica The uterus was small, and the endometrium normal in thickness The pituitary gland was normal in size On either side of the trachea, embedded in scar tissue, small nodules of thyroid tissue were found The liver was enlarged, its cut surface showing centrilobular congestion

Histology

The tumour was a poorly differentiated polyhedral cell carcinoma of the adrenal cortex, with a scanty stroma (fig 3) The cells were large, with abundant eosinophil and faintly granular cytoplasm and large round or oval nuclei usually with prominent nucleoli Mitoses were uncommon, and there was some necrosis The mass in the vena cava, right atrium, and pulmonary artery consisted of tumour with a little superficial thrombus The cytoplasm contained a little sudanophil lipoid irregularly distributed throughout the tumour Broster and Vine's ponceau fuchsin stain showed fuchsinophil granules very irregularly distributed, within the cells were very occasional granules which stained with periodic-acid-Schiff and proved to be glycogen by the diastase control method The left adrenal cortex was much atrophied, especially the zona fasciculata The cells were packed with sudanophil lipoid, except a narrow zone at the outer part of the zona glomerulosa Ponceau fuchsin staining did not show fuchsinophil granules, occasional cells containing granules stained by periodic acid Schiff were seen in the zona fasciculata

The pituitary gland showed marked alteration of the basophil cells, which were hypertrophied and vacuolated, and 60% of them were hyalinised (Crooke 1935) This hyalinisation was most clearly shown by periodic acid Schiff staining and affected both central and peripheral cells, sparing only those basophils posterior to the intermediate cleft Many of the affected cells were completely hyaline, with practically unstained cytoplasm, within which vacuolation was still present A few cells of the general size, shape, and nuclear configuration of basophils had very clear cytoplasm within which were a few large granules and rods which stained with periodic acid Schiff, such cells were confined to the central portion of the gland Gomori's aldehyde fuchsin stain also showed the hyalinisation, and some basophils were not stained This method was also capricious in differentiating basophils into stained (β basophils) and unstained (α basophils), hence evidence of localisation of either type of cell at the periphery or centre of the gland was lacking Both types of granule, with or without hyaline change, sometimes occurred in the same cell 20% of the cells classified as "chromophobe" from the Mallory stain contained material which took the periodic acid Schiff stain The distribution of this varied from a few large vesicles to a diffuse granulation within the cytoplasm Many of the finely granulated cells resembled small basophils, but none showed hyalinisation Occasional acidophils contained a minute body which took the periodic acid Schiff stain, usually paranuclear in position Phospholipid within the acidophils was normal in amount, the only change noted being a slight degranulation compared with control sections stained on the same slide

Discussion

Adrenal cortical overaction in the adult female commonly presents either as Cushing's syndrome or as the adrenogenital syndrome (Taylor 1955) The adrenogenital syndrome has been defined by Hartman and Brownell (1949) as (1) disturbance and cessation of menstruation, (2) hypertrichosis of face, limbs, hands, feet, and trunk, (3) deeper and coarser voice, (4) enlargement of the external genitalia, degeneration of the ovaries, and diminution in size of the uterus, (5) alteration of bodily contour, which becomes short, thickset, broad shouldered, deep chested, and narrow hipped, and (6) underdevelopment of breasts and obesity Hartman and Brownell emphasise the rarity of adrenal tumours as a cause of this condition

The onset of the Cushing adrenogenital syndrome in our patient dated from the thyroidectomy, this may be interpreted as a "release" of the adrenal cortical steroids produced by the carcinoma, and which—before thyroidectomy—could not produce their characteristic effects The progression of events is similar to that seen in the rat and guineapig by Aterman and Greenberg (1954) who found that thyroid hormone inhibited cortisone induced exophthalmos and modified the characteristic signs of hypercorticism, such as atrophy of the adrenal glands and involution of the thymus Also, thyroidectomy in rats accentuated the signs of hypercorticism or allowed these signs to appear at a lower level of cortisone administration In the case described, transition from a slightly hyperthyroid state to a hypothyroid state led to the appearance of florid symptoms of hypercorticism

The adrenogenital syndrome and Cushing's syndrome can be combined in the same patient, Lucas et al (1955) describe the case of a 34-year old mother of two children with an adrenogenital syndrome due to carcinoma of the left adrenal cortex The tumour was removed but recurred a few months later, this time associated with Cushing's syndrome The patient died five months after the original operation

The only other published case related to thyroidectomy that we have been able to find was described by Hurxthal and Musulin (1953) A man, aged 25, presented with an illness which, in retrospect, was believed to be a Cushing syndrome Thyroidectomy was done, and the patient became much worse, he became fatter and much more weak, and sluggish, and developed generalised osteoporosis with many pathological fractures He died after exploratory craniotomy, necropsy findings are not mentioned The mode of progression of this case is very similar to that of the one recorded above the intact thyroid gland appeared to be controlling or suppressing the symptoms, and thyroidectomy led to the "release" of the abnormal adrenal cortex and the appearance of much more pronounced symptoms of hypercorticism The present case and that of Hurxthal and Musulin (1953), with their similar modes of progression, suggest that this hormonal pattern is of fundamental importance in the adrenogenital syndrome and Cushing's syndrome

We have no direct evidence that the tumour was present before thyroidectomy, but, in view of its massive size five months later and the natural history of this type of growth, there is very little doubt that it was already in existence

The pituitary cytology is of interest There was no selective damage to the central mass of basophils which correspond in position with the thyreotrophs (β basophils) of the rat There were, however, central clear cells which correspond very closely in morphology to the "thyroidectomy cell" of the rat (Purves and Griesbach 1951) and may indeed be of a similar nature

Summary

A case of mixed adrenogenital Cushing syndrome is presented

The precipitating factor is believed to have been thyroidectomy, with the "release" of adrenal cortical secretions, and the appearance of the characteristic symptoms of hypercorticism

Cells like the rat "thyroidectomy-cell' were found in the pituitary gland

We thank Prof F A R Stammers, under whom the patient was admitted, for permission to publish, and Prof J W Orr for valuable advice and criticism

ACUTE OSTEOPOROSIS WITH HYPERCALCÆMIA

A STUART MASON

M.A, M.D Camb, M.R C.P

SENIOR LECTURER IN MEDICINE,
MEDICAL AND ENDOCRINE UNITS, LONDON HOSPITAL

OSTEOPOROSIS, as an intrinsic disorder of bone, is associated with normal serum-calcium and serum-phosphorus levels The finding of a raised serum-calcium level with radiological evidence of osteoporosis strongly suggests that the disorder of bone is secondary to a disturbance of calcium metabolism such as hyperparathyroidism (Cooke 1955)

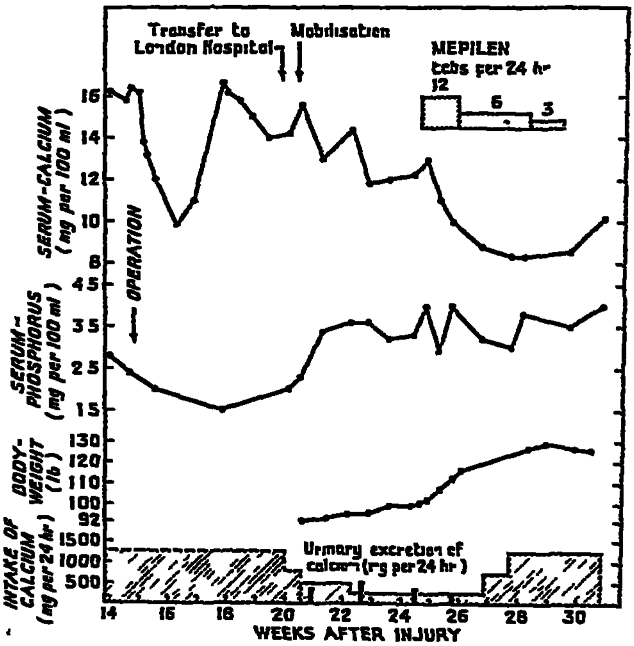
Albright et al (1941) reported osteoporosis with a raised serum-calcium level in a boy, aged 14, with a fractured femur The initial diagnosis of hyperparathyroidism was discarded when exploration of the neck and mediastinum did not reveal a parathyroid tumour It was concluded that the bony injury and subsequent immobilisation were responsible for the osteoporosis and hypercalcæmia When the patient was mobilised the serum-calcium level returned to normal A similar case, also cured by mobilisation, was reported by Halvorsen (1954)

I report here an example of the syndrome in a young adult

Case-report

A woman aged 22 was admitted to another hospital on Oct 15, 1955, after a motor accident Examination revealed a comminuted fracture of the left side of the pelvis a crush fracture of the third lumbar vertebra, and a lesion of the cauda equina which caused weakness of the right leg and almost complete paralysis of the left leg, the bladder and anal sphincters were also affected

Treatment and Progress—Skin traction was applied to the left leg for six weeks When this was discontinued, a back slab was applied to the leg and physiotherapy was started This was confined to passive movement and faradic stimulation of the lower limbs Three weeks after injury the patient lost her appetite and was given milk instead of solid food She became progressively more thirsty and drank up to eight pints of milk daily A week later she started to vomit, and her pulse rate rose to 120 Her general condition steadily deteriorated loss of weight being constant and severe Fourteen weeks after injury her weight had dropped by 50 lb the tachycardia was persistent, and anorexia, vomiting lethargy, and muscular weakness were predominant There was also obstinate constipation, which caused fæcal impaction on one occasion Radiography showed osteoporosis of her legs lumbar spine and pelvis Her urine which had become infected soon after her injury, contained pus despite constant and varied treatment Her blood urea level, which had been normal on three previous occasions was 39 mg per 100 ml



Her serum-calcium level was 16 2 mg per 100 ml, serum-phosphorus 2 8 mg per 100 ml, and alkaline phosphatase 9 0 K. A units

Operation—When the presence of hypercalcæmia had been confirmed on succeeding days, the parathyroid glands were explored on Jan. 28, 1956 but no adenoma was found One parathyroid gland was removed but was found normal on histological examination

Postoperatively the serum calcium level fell rapidly (see figure) and the patient's condition much improved, but this improvement was short-lived and all the previous symptoms returned two weeks after the operation, and the serum-calcium which had been 9 8 mg per 100 ml nine days after the operation, rose again to 16 0 mg per 100 ml The patient was transferred to the London Hospital on March 2, 1956, nineteen weeks after her original injury

On admission she was very ill and wasted, weighing 92 lb and having a pulse rate of 110 and gross atrophic palsy of the legs, particularly the left leg and buttock Her bladder did not empty completely, and her urine was infected

Investigations—Her blood contained sodium 148 m eq per litre, chloride 96 m eq per litre, bicarbonate 35 m eq per litre, potassium 4 6 m eq per litre, urea 48 mg per 100 ml, plasma proteins 8 4 g per 100 ml., alkaline phosphatase 3 0 K.-A units (on three occasions), calcium 14 2 and 15 6 mg per 100 ml, phosphorus 1 9 and 2 3 mg per 100 ml (at this level the rate of urinary excretion of phosphate was 0 2 mg a minute) The urinary excretion of calcium was 383 mg in twenty four hours Radiography showed osteoporosis of the legs, pelvis, and lumbar spine The original fractures had not healed The skull showed no radiological abnormality, and there was no evidence of renal calculi or of nephrocalcinosis

Treatment and Progress—In view of the absence of increase in serum phosphatase level the high serum calcium level could not be attributed to hyperparathyroidism but seemed more probably the result of bony fractures and immobilisation An intensive programme of active movements was therefore started Although the patient's legs were capable only of minimal movement her activity was increased rapidly by exercising all the other muscle groups At the same time her intake of calcium was reduced to 500 mg daily and, two weeks later, to 250 mg daily On this regime she made steady progress vomiting and thirst disappeared, her appetite returned and her weight increased The serum-phosphorus level quickly rose to normal, but the serum-calcium fell slowly until it remained steady at 12 mg per 100 ml The calcium balance remained negative, the urinary excretion of calcium being 372 mg in twenty four hours after two weeks on an intake of 250 mg in twenty four hours This failure to return to complete normality despite adequate mobilisation, was evident twenty five weeks after the patient's injury In a further effort to improve the calcium metabolism

'Mepilin' (ethinyl œstradiol 0 01 mg with methyl testosterone 3 mg per tablet) was administered in an initial dose of 12 tablets daily This treatment produced a rapid rise in weight and a drop in serum-calcium level to 8 4 mg per 100 ml The urinary output of calcium also fell to normal, and the alkaline phosphatase level rose to 6 0 K A units Since the patient's weight continued to rise and her general condition was very satisfactory, the dose of mepilin was decreased and the intake of calcium increased The serum calcium level then returned to normal, and the patient's subsequent progress was only interrupted by an attack of pyelitis Her left ankle required manipulation to restore free movement, but then she could walk well without a stick

Discussion

Within four weeks of injury this patient developed anorexia, vomiting, thirst, constipation, tachycardia, and progressive loss of weight The cause of these symptoms, which had persisted for ten weeks, was attributed to hypercalcæmia The raised serum-calcium level and lowered serum phosphorus level prompted a search for a parathyroid tumour Removal of one parathyroid gland and examination of the others was followed by a transient disappearance of the hypercalcæmia However, the disturbance recurred, suggesting either a parathyroid adenoma in the mediastinum or some other cause of the hypercalcæmia

In appraising the situation nineteen weeks after injury it was noted that the raised serum-calcium level was associated with an alkaline-phosphatase level at the lower limits of normality, and that the lowered serum phosphorus level was accompanied by a normal rate of urinary excretion of phosphorus Furthermore the radiological evidence of osteoporosis was confined to the area of injury and of immobilisation, nor were there any specific radiological signs of hyperparathyroidism These points, taken in conjunction with the patient's initial bony injury and subsequent immobility, led to the diagnosis of acute osteoporosis with hypercalcæmia The appropriate treatment, active movement and restricted intake of calcium (Albright et al 1941) proved partially successful Therapy with œstrogen and androgen, as suggested for postmenopausal osteoporosis (Albright et al 1940), caused an immediate increase in osteoblastic activity with a fall in the serum calcium level, a decrease in the urinary output of calcium, and a rise in the alkaline phosphatase level This good clinical response indicated the effectiveness of hormone therapy in a case of bony atrophy from disuse, confirming the experimental findings of Armstrong et al (1945)

The changes in calcium balance which follow bony injury and immobilisation were studied by Howard et al (1945), who found that the urinary loss of calcium increased for four weeks and continued at a maximal rate for at least two months, and that the loss of nitrogen was maximal within a few days and disappeared within a month This work supported the contention of Albright et al (1941) that immobility was a more important factor than the initial injury in producing a negative calcium balance The prime importance of immobilisation was proved by the observation of a sustained loss of calcium in healthy men encased in plaster (Dietrick et al 1948) This effect is confirmed by the radiological demonstration of osteoporosis in the legs of all patients immobilised for three or more months (Stevenson 1952)

Only a small amount of activity is required to inhibit the loss of calcium from immobilisation, healthy men encased in plaster do not develop a negative calcium balance if placed on a rocking bed (Dietrick 1948) The patient whose history is recorded here was never fully immobilised by splinting but did not respond to mobilisation so satisfactorily as the patients of Albright et al (1941) and Halvorsen (1954) The major difference between their patients and the present one lies in her neurological lesion, which prevented active movements of her legs Wilkins (1945) reported losses of calcium up to 1 g daily in patients with poliomyelitis, and Orr (1941) reported a serum-calcium level of 18 mg per 100 ml in a child with poliomyelitis Furthermore the use of a rocking bed does not prevent loss of calcium in a paralysed patient (Wyse and Pattee 1954)

Immobilisation causes atrophy of bone because it removes the stresses of movement which are the normal stimulus to osteoblastic activity Healthy bone is in a constant state of flux, bone deposition balancing resorption, hence a cessation of osteoblastic activity due to immobilisation allows resorption to continue and leads to osteoporosis In the rare cases of osteoporosis with hypercalcæmia, such as the one described here, the resorption of bone must be very rapid to allow so much calcium to enter the circulation Hence the condition is unlikely to arise unless the bone was previously in a state of rapid metabolism Paget's disease provides an example because both the formation and the destruction of bone proceed more rapidly than normal If a patient with Paget's disease is immobilised, acute osteoporosis with hypercalcæmia develops (Albright and Reifenstein 1948) Similarly the increased metabolic activity of young bone compared with the adult skeleton (Leblond and Greulich 1956) probably explains why hypercalcæmia after immobilisation alone is confined to children But these observations do not explain the sustained hypercalcæmia in the present patient, who had no previous bone disease and was fully grown

In the present case it seems possible that there may have been a breakdown in the homœostatic relationship between the blood-calcium level and the activity of the parathyroid glands Under physiological conditions the rate of secretion of the parathyroid hormone varies inversely with the serum-calcium level (McLean 1956) Hence the hypercalcæmia due to skeletal immobilisation should be self-limiting owing to inhibition of parathyroid function In this patient, however, hypercalcæmia persisted although the parathyroid glands were structurally normal Indeed the only occasion when the blood-calcium level fell was after operative exploration at which one parathyroid gland was removed—i e , when, on the analogy of subtotal thyroidectomy, a temporary inhibition of parathyroid secretion may have been induced If this is true, the reappearance of hypercalcæmia would coincide with the resumption of secretion of the parathyroid hormone If indeed there was in this patient a breakdown in the homœostatic relationships between the serum-calcium level and the secretion of the parathyroid hormone, we have no evidence to suggest the reason for the breakdown or for the restoration to normal which took place when the negative calcium balance was corrected by mobilisation and hormone therapy

Summary

A case of acute osteoporosis with hypercalcæmia in an adult without previous bone disease was successfully treated by mobilisation, restricted intake of calcium, and hormone therapy

It is suggested that a breakdown in the normal homœostatic control by the parathyroid glands was responsible in some measure for this syndrome

I am deeply indebted to Dr J Kidd for the early records of this patient and his kindness in transferring her to the London Hospital, to Mrs E Scott and her staff for nursing and dietetic care of the patient, and to Mrs M N Hryniewicz for the biochemical work

PERFORATION and hæmorrhage are said to complicate about 6% of perforated ulcers Uncommon chronic perforations into aorta, portal vein, pleura, pericardium, heart, and other organs have been reported In the case described here a benign gastric ulcer was associated with hæmorrhage and had perforated into the spleen

Case-report

A white man, aged 36, had had, from 1946 to 1951, attacks of epigastric burning pain after meals and pyrexia (102°F) of several days' duration

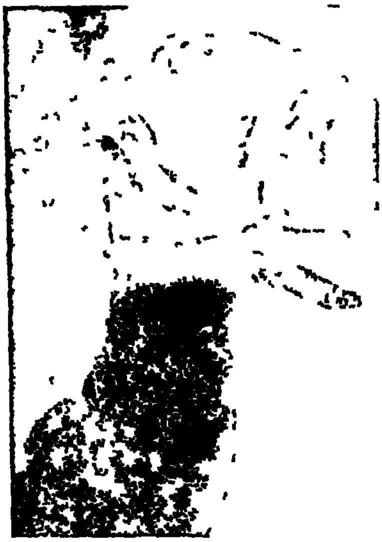

Fig 1—Stomach showing barium level and gas bubble on its left side

On admission on April 5, 1951, he had severe melæna hæmatemesis, and consequent anæmia Radiography disclosed a strange barium level and gas bubble on the left side of the stomach (fig 1) This cavity filled with barium from the stomach when the patient bent over to his left Urography and an opaque enema showed no relations of colon or kidneys with the cavity At exploratory laparotomy no lesion was found, and the patient was discharged

A year later, in 1952, he had another hæmatemesis and melæna This time he underwent subtotal gastrectomy, but the abnormal barium level and gas bubble still appeared to the left of the resection

On April 10, 1956, after three and a half years of calm, he had a sudden severe melæna, with anæmia (2,000,000 red cells per c mm) He was given a blood transfusion and operated on

On laparotomy the stump of the duodenum appeared normal, and no jejunal ulcers were found On the greater curvature were thick adhesions to the spleen and the splenic flexure of the colon The spleen was large and divided into two lobules, diffuse perisplenitis made it adherent to the peritoneum of the abdominal wall The splenic flexure of the colon was bound to the spleen by the same fibrotic process These adhesions were freed with difficulty and the spleen was exteriorised but, when this had been done, the greater curvature of the stomach was seen to fit into the spleen's hilum Longitudinal gastrostomy revealed an ulcer situated high on the greater curvature, perforating into the hilum of the spleen, and having a crater 1 cm wide The spleen was removed and the gastrostomy closed, and the patient recovered uneventfully

Pathology

The spleen measured 11 × 8 × 5 cm and was deeply indented on its external wall Its hilum was covered by a rhomboidal segment of gastric wall, whose centre corresponded to an ulcerous niche 20 mm across and 2 mm deep (fig 2) Section revealed a fibrotic bed, with large blood vessels, continuous with fibrotic intrasplenic tissue The niche was covered almost completely by simple cylindrical gastric epithelium There were a few small areas without epithelium, probably the remains of a primitive ulcer Nearby and beneath the epithelised area were large blood spaces, covered with thin endothelial walls, and arteries, resembling an angioma Thick bands of connective tissue containing much iron pigment invaded the splenic parenchyma

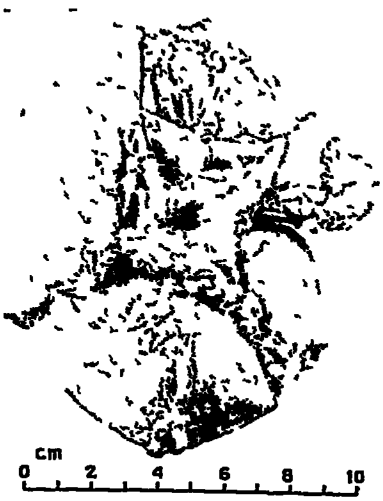

Fig 2—Spleen with adherent gastric wall

Summary

A case is reported in which a benign chronic ulcer of the greater curvature of the stomach perforated into the hilum and parenchyma of the spleen

This ulcer was not found at operation for subtotal gastrectomy A second operation revealed the ulcer which had provoked massive severe hæmorrhage by damage to the splenic vessels

electrocardiographic tracings in our case over a period of four months

Case-report

A woman aged 28 was first seen in her own home for an influenza like illness 5 days previously she had taken suddenly ill, with sore throat, fever, headache, profuse sweating, cough, and sharp pains in the chest Her parents were the only other occupants of the house, and her mother had similar symptoms of the same duration, and was confined to bed in an adjacent room Her father, though ambulant, had malaise, headache, cough, and sweating attacks

The daughter's temperature was 100°F and the skin was moist There were fine crepitations at both lung bases, the pulse was slow and irregular, and a pericardial friction rub was audible over the precordium The heart sounds were normal, and there were no murmurs, blood pressure 140/80 mm Hg The fauces were inflamed but no vesicles were seen The mother was also examined and was found to have a pericardial friction rub and a temperature of 100°F The father was not examined The patient was admitted to hospital next day for investigation Her parents declined further study, and remained at home

On admission, the patient's temperature had fallen to 98°F, and she had no further pyrexia The basal crepitations had completely cleared up on the 3rd day after admission The pericardial friction rub persisted for a further 3 weeks, but she was symptom free a few days after admission Radiography of chest showed normal heart shadow and clear lung fields (day of admission), repeat radiography and fluoroscopy at weekly intervals during her 29 days in hospital showed no evidence of pericardial effusion, or any other abnormality White cell count 3500 per c mm Blood sedimentation rate (Westergren) 27 mm in the first hour on day of admission, 10 mm on 6th day Mantoux negative (1 in 1000) Throat swab *Streptococcus viridans*, pneumococci, *Neisseria catarrhalis* Samples of the patient's convalescent serum were submitted to the Virus Reference Laboratory, Colindale, London, for virus antibodies, and titres obtained are shown in the accompanying table These results indicated a type-B4 Coxsackie infection

Because of the evidence of cardiac involvement, serial electrocardiograms were recorded during the patient's stay in hospital and thereafter at follow up examinations as an out patient for 3 months In addition to evidence of pericarditis, there was a persistent extrasystolic arrhythmia, the ectopic focus apparently situated in the A–V node Fig 1 is from lead 2 recorded on the day of admission It shows sinus arrhythmia, complicated by a non compensatory extrasystole, which disturbs the basic sino auricular rhythm by retrograde auricular activation closely related in time to its ventricular complex This appears to indicate that the ectopic focus is situated in the A V node, the ventricular complex being moderately aberrated The T waves are inverted—that of the beat following the extrasystole more than the others Fig 2 was recorded 3 weeks later It differed in no way from previous serial tracings The extrasystolic arrhythmia persists, and the significant abnormality is the negativity of the T waves in leads 2, 3, and V_3–V_6 Subsequent serial tracings over the following 2 months resembled fig 2 Thereafter the extrasystoles diminished in number, and after a further few weeks the electrocardiogram reverted to within the normal range

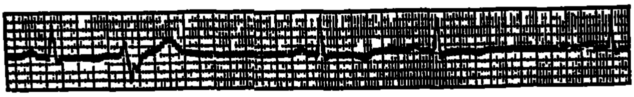

Fig 1—Coxsackie pericarditis Lead 2 (time marker 0 02 sec) Sinus arrhythmia with nodal extrasystole Abnormal T waves, more negative in post-extrasystolic beat.

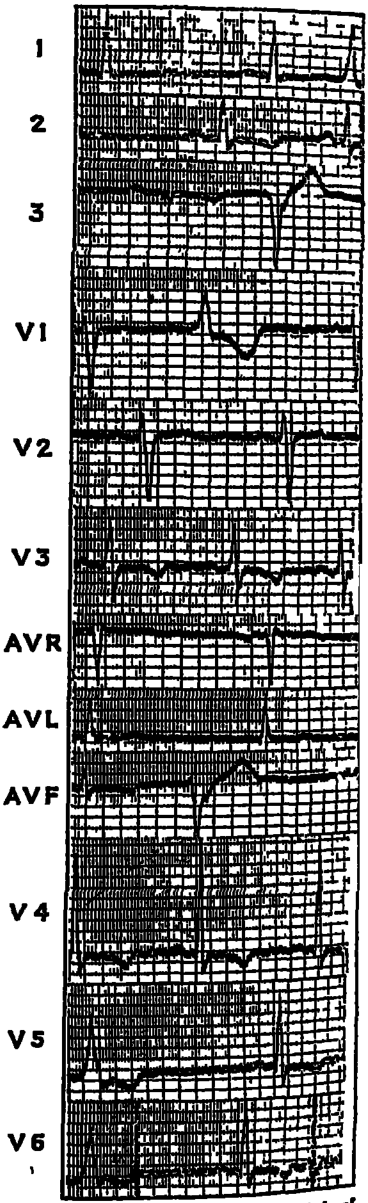

Fig 2—Coxsackie pericarditis End of third week Extrasystolic arrhythmia T negative in leads 2 3, and V_3V_6 (time marker 0 02 sec)

Discussion

Little is known about the pathogenesis of Coxsackie-virus infection in man Herpangina has been attributed to group-A Coxsackie-virus infection, and pleurodynia and aseptic meningitis to group B Viruses of group B4 have lately been isolated from the heart muscle in fatal myocarditis in newborn babies (van Creveld and de Jager 1956, Verlinde et al 1956) The viruses are probably universally distributed, and they have been isolated from sewage and flies (Jawetz et al 1956) Household exposure is important, and it is significant that the parents of our patient had a febrile illness at the same time Group B infection is usually associated with clinical illness, and it appears very likely that the case described—with a few days' fever and evidence of pulmonary and cardiac involvement—was related to the high titre of subgroup B4 There is no specific treatment The unique feature in our patient was the benign pericarditis, and possibly also myocardial involvement producing the persistent extrasystolic arrhythmia The electrocardiographic abnormalities remained in our case for some months after clinical recovery As Coxsackie virus infection may produce only minor symptoms which may be overlooked or forgotten by the patient, the discovery of abnormal electrocardiographic tracings, especially with regard to T wave changes in an otherwise healthy young adult, may raise the question of an unrecognised virus infection some months previously

Summary

A case of benign pericarditis is described in which it seemed very likely that infection with Coxsackie virus, ubgroup B4, was the cause Symptoms lasted only a ew days, but clinical signs of pericarditis persisted for ome weeks, and abnormal electrocardiographic records were present for some months As Coxsackie infection may produce only minor illness which may be overlooked, the possibility of its occurrence should be borne in mind when otherwise healthy young adults have abnormal electrocardiograms

We wish to acknowledge the valuable help of the Virus Reference Laboratory, Colindale London, and the useful advice and criticism of Dr C Cotton Kennedy, consultant clinical pathologist, Belfast City Hospital

Preliminary Communication

A NEGLECTED SOURCE OF BLOOD-GROUP ANTIBODIES

FOR practical purposes the supply of rhesus (and other) antibodies comes from the serum of women who have been immunised by pregnancy They are usually of the common anti-D variety Less frequently antibodies are found in patients of either sex who have received repeated transfusions of blood containing antigens they themselves lack These are more likely to be the less common anti-E, anti-C, or anti-c, since they may arise in Rh(D)-positive recipients of blood which, although D-positive, is not necessarily compatible for the antigens E, C, and c

Only limited amounts of serum can be obtained from such people Clinicians are often reluctant to allow their obstetric patients to donate in the puerperium, even with the promise of compatible blood to replace any withdrawn

A large number of repeatedly transfused Rh(D)-positive patients will receive C or E or c incompatible blood, and immunisation particularly to the latter two, is to be expected in a few but often these patients have one or other of the blood dyscrasias, and their clinical condition rarely justifies venesection for the purpose of preparing test sera

Any additional source of antibodies therefore becomes of great value, especially when it can be obtained in really large quantities and with no inconvenience to the donor

The ascitic fluid from patients with such conditions as cirrhosis of the liver, who have received multiple transfusions and become immunised to a blood group antigen may form such a source It is surprising that this has received so little attention in the past There is practically nothing in the voluminous literature on the subject of blood group antibodies to suggest that the possibilities of this "by-product" have been properly explored Pickles,[1] however refers to the presence of the antibody Yt^a in a case of ascites and, in a personal communication describes an anti-c in the ascitic fluid of an R_1R_1 patient immunised by pregnancy

CASE REPORT

A female, aged 58, group O Rh positive and suffering from cirrhosis of the liver with œsophageal varices received several uneventful blood transfusions in 1956 Nothing unusual was found on cross matching until October of that year when she was found to be incompatible with one of four bottles of group-O Rh positive blood prescribed for her At this stage her genotype was determined as R_1R_1 (CDe/CDe), those of the three compatible bottles as R_1R_1 (CDe/CDe) or R_1r (CDe/cde) and that of the fourth the incompatible bottle as R_2r (cDE/cde) As was expected, her serum contained the antibody E

Her ascitic fluid was examined for anti-E, and this was found in appreciable amount, the best results were obtained by Löw s papain technique, visual reactions appearing in tubes incubated for an hour at 37°C Surprisingly good results were also obtained by Stratton s[2] "sandwich" technique, but with Löw s papain substituted for albumin[3]

Many litres of this valuable fluid have already been obtained, and, since her cirrhosis yields four or five litres of ascitic fluid a month, the supply of antibody is at present limitless

With the patient's consent and her doctor s coöperation, bi-weekly injections of EE (R_2R_2) blood are being given intravenously to boost the titre of her serum and, it is hoped, of her ascitic fluid The antibody appears to be fairly stable and can be stored frozen or freeze dried. It withstands at least twenty freezings and thawings and it has been reconstituted from the dried state without loss of potency

COMMENT

A programme of ab-initio immunisation of other cases of ascites has been planned Meanwhile, it is suggested that the serum and ascitic fluid of any patient with ascites who has had multiple blood-transfusions should be examined for the presence of the rarer Rh and other blood-group antibodies If only a fraction of 1% is found to be immunised the large yields of reagent will be ample compensation for the work involved

I have great pleasure in acknowledging the enthusiastic coöperation of Dr T C Jameson Evans, who has charge of the case, and of Dr C C Thomas, group pathologist, Farnham County Hospital, Surrey

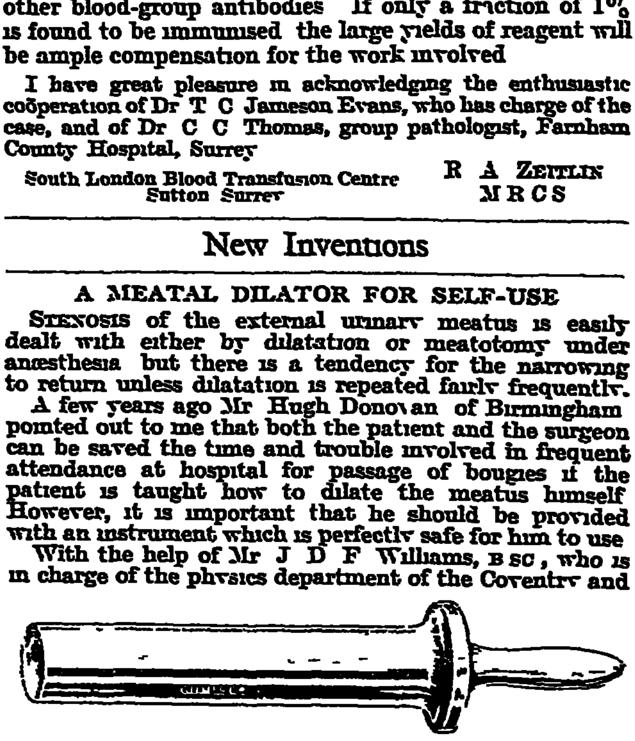
New Inventions

A MEATAL DILATOR FOR SELF-USE

STENOSIS of the external urinary meatus is easily dealt with either by dilatation or meatotomy under anæsthesia but there is a tendency for the narrowing to return unless dilatation is repeated fairly frequently.

A few years ago Mr Hugh Donovan of Birmingham pointed out to me that both the patient and the surgeon can be saved the time and trouble involved in frequent attendance at hospital for passage of bougies if the patient is taught how to dilate the meatus himself However, it is important that he should be provided with an instrument which is perfectly safe for him to use

With the help of Mr J D F Williams, B SC, who is in charge of the physics department of the Coventry and Warwickshire Hospital, I have devised a small instrument which has proved very satisfactory for this purpose It is made from 'Perspex,' has a very smooth surface, is boilable, and has a flange so that the instrument can only be passed for a limited distance The size of the instrument corresponds to 18 Ch, and this size has in practice, been found to be the only one necessary. After the initial dilatation the patient is given one of these instruments together with a supply of sterile water-soluble lubricant and is instructed how to cleanse the penis with dilute 'Dettol' solution and to introduce the instrument after it has been sterilised by boiling At first the instrument is used daily, but with the passage of time it is used at increasing intervals In many cases the tendency for the meatus to contract seems to disappear after a few months, and the patient, if reasonably intelligent can usually be left to determine how often he should introduce the dilator



The instrument has been made for me by the Genito-Urinary Manufacturing Company 28A, Devonshire Street, London W 1

Reviews of Books

The Child and the Outside World

Studies in Developing Relationships D W WINNICOTT, F R C P Edited by JANET HARDENBERG, M B London Tavistock Publications Ltd 1957 Pp 187 16s

IN several papers which form the main body of this collection, Dr Winnicott shows how the evacuation of town children to the country in war-time led to deeper understanding of the needs of children deprived of home life The evacuated children were all at first sent to private homes, but under the stress of separation from their families many became psychologically ill The experience gained in providing hostels for these children has greatly influenced the care given to children who, in peace-time, cannot be looked after at home It is clear how great a part Dr Winnicott has played in applying war-time understanding to peace-time difficulties

Those concerned with children who have to live away from home will find much to help them, and those whose responsibility is "placement" or "disposal" will find encouraging support for the view that "home is best" Since many of the children reacted to their deprivation by antisocial behaviour, the work in hostels has also had an important bearing on the treatment of juvenile delinquents

In quite another vein is the lecture to the 8th form of St Paul's School—Towards an Objective Study of Human Nature This little masterpiece should certainly be read by anyone seeking a simple and lucid description of what psycho-analysis is about

But this leads us to the paradox of Dr Winnicott's writings on the one hand, there is a deep understanding of the strong unconscious forces of love and hate at work in all children, and, on the other, the concept of a "normal" parent who has come to terms with his unconscious forces in a way which is seldom, if ever, found The standard for "normal" parental behaviour and feeling appears to be unattainable and may not even be desirable

The Visual Fields

A Textbook and Atlas of Clinical Perimetry DAVID O HARRINGTON, A B, M D, F A C S, clinical professor of ophthalmology, University of California School of Medicine London Henry Kimpton 1956 Pp 327 £6

THIS book may well become a successor to Traquair's famous monograph Professor Harrington, like the late H M Traquair, is an ophthalmologist with a deep interest in neurology, and his book shows Traquair's influence, particularly in the description of techniques for examining the visual fields

Simple non mechanical methods are Professor Harrington's first choice, but he has experimented with and accepted several novel procedures which more conservative schools would do well to examine For example, he has been able to eliminate many of the drawbacks of the older methods by using ultra violet illumination and fluorescent test objects for his perimetry and scotometry He has elaborated an ingenious system by which large numbers of subjects can be quickly screened—an outstanding need for busy eye clinics Patients fix the centre of a series of ten cards and are asked to describe the simple patterns which fluoresce for $^1/_4$ sec Incorrect answers lead to more extensive tests by orthodox methods

The second part of the book is devoted to the interpretation of defects in the visual fields, with chapters on each part of the visual pathway and many excellent diagrams of abnormal fields Where possible anatomical pictures indicate the proven position of the lesion Much effort has been spent on clear classifications, some of which are original Vast experience clearly lies behind the discussion of the many illustrative cases, but the uninitiated are kept constantly in mind Many full page illustrations show diagrammatically the field defects which can result from lesions at various anatomical levels The author's laudable attempt to keep the book self explanatory makes for rather dull reading in places and his style sometimes suffers for the sake of teaching

This is an excellent textbook for the beginner who intends to take visual-field testing seriously It has a good index and a fairly full bibliography and is therefore a useful reference book as well

Social Policies for Old Age

A Review of Social Provision for Old Age in Great Britain B E SHENFIELD, formerly a lecturer in social studies at Birmingham University London Routledge & Kegan Paul 1957 Pp 236 25s

BY gathering together much information, statistical and sociological, that has hitherto been hidden in various blue-books, Government publications, surveys, and elsewhere, the author has done a useful service Few doctors derive much regular intellectual nourishment from such sources, and many will be grateful for the help of this book

It sets out to present, in relation to the general problems of old age, the basic facts upon which social policies should be founded, and it succeeds A short but illuminating account of the demographic factors that underlie the recent rise in the number and proportion of old people in the population is followed by a long discussion of employment for the older worker and pensions Finally, the author deals with housing and the pattern of medical and other services available for domiciliary care

Her book will have a wide appeal, particularly to doctors and social workers concerned with old age who wish to enlarge their outlook on the subject

Manual of Anesthesiology

For Residents and Medical Students HERMAN SCHWARTZ, M D, S H NGAI, M D, E M PAPPER, M D, from the Anesthesiology Service, Presbyterian Hospital, New York Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 170 32s 6d

UNLIKE most of its counterparts in this country, this introduction to the subject of anæsthesia concentrates on the scientific rather than the purely practical aspects, and in doing so it provides a good balance between the basic sciences and their applications to anæsthesia The text is derived from talks given to beginners and it effectively fulfils its aims of supplementing practical theatre work and encouraging the reading of original papers

Group Psychotherapy

The Psycho Analytic Approach S H FOULKES, M D, physician to the Bethlem Royal and Maudsley Hospitals, E J ANTHONY, M D, senior lecturer in child psychiatry, University of London, physician to the Bethlem and Maudsley Royal Hospitals Harmondsworth, Middx Penguin Books Ltd 1957 Pp 263 3s 6d

A CLEAR and comprehensive account is here provided of a method of psychotherapy that is making rapid strides and attracting much interest in psychological circles

In the first part of the book an introductory survey traces the history of group psychotherapy and relates the various methods since developed to the theories held by their authors. In the next three chapters, the group structure, the therapeutic process, and the technical and practical aspects of the treatment are discussed from the standpoint of group analysis, the method developed by Dr Foulkes in 1940

The second part is devoted to clinical illustrations with a commentary, and the third to chapters on the natural history of the therapeutic group, the phenomenology of the group situation, general dynamic theory and "metatheory" (speculations on theoretical and practical developments)

This book will inform the novice and stimulate the expert in this or other kinds of psychological treatment

---

Physiopathology of the Reticulo-endothelial System (*Oxford Blackwell Scientific Publications* 1957 Pp 314 45s)—Among the participants in this symposium organised by the Council for International Organisations of Medical Sciences were Prof A A Miles, who spoke on local defences against infection in relation to the general reticulo endothelial defences, and Dr P G H Gell, who discussed the nature of some tissue hypersensitivity reactions The papers, edited by Dr B Benacerraf and Dr J F Delafresnaye, under the direction of Dr B N Halpern, are in English, there are summaries of each, and an introduction to the conference in French

THE LANCET

LONDON SATURDAY, MAY 4, 1957

Pulmonary Hypertension

THE many clinical features related to pulmonary engorgement, and the finding of atheromatous plaques in the pulmonary arteries at necropsy, led our predecessors to deduce that the pulmonary vascular pressure was raised in mitral stenosis as well as in other forms of left-sided heart-failure This was confirmed and put on a quantitative basis just over a decade ago when a cardiac catheter was first purposely passed into the pulmonary artery[1] Since then measurement of the pulmonary-artery pressure has become commonplace in all modern cardiological departments, and appreciation has grown apace of the circumstances in which pulmonary hypertension arises, and of the natural history of its various forms Clinical and laboratory assessment has led to renewed interest in the physiology of the pulmonary vessels, and opportunities are taken during catheterisation to gain information on such important matters as the innervation of the pulmonary vessels The results of these investigations are controversial Some suggest that the pulmonary vascular pressure-resistance may fall considerably under the influence of ganglion-blocking drugs[2] or minute doses of acetylcholine[3] given through a catheter into the pulmonary artery This supports the view, taken by **DALY**[4] after many years of painstaking study, that the pulmonary arterioles have an active autonomic innervation But in the treatment of patients with severe pulmonary hypertension ganglion-blocking drugs have failed, and **LEE** et al[5] have shown beyond any doubt that the pulmonary arterioles are not constricted in some of the baroceptor pressor reactions in which sympathetic vasoconstriction in the systemic vessels is easily demonstrated Yet, although the sympathetic innervation of the lung arterioles does not readily come into action in healthy people, it may become more active in pathological states

In mitral stenosis the rise in pulmonary arterial pressure is not always due to simple passive transmission of pressure from the left atrium Moderately raised at first, the pressure tends to become very high on moderate exercise, and later it may become persistently elevated at a level about or even above that in the systemic arterioles[6] This extreme pulmonary vasoconstriction is thought by some to protect against pulmonary œdema from extreme rises in alveolar capillary pressure , but this explanation tells us nothing of the mechanism Others believe that pulmonary œdema is not uncommon in the presence of extreme pulmonary hypertension[7]

In bronchitis and emphysema the pulmonary arterial pressure is at first raised only during acute exacerbations of bronchitis with intensification of cyanosis, and the pressure falls to normal when the attack passes off[8] In the more advanced stages of emphysema the pressure becomes more persistently raised between attacks The early reversibility of bronchitic pulmonary hypertension yielded a new concept of functional and reversible pulmonary hypertension, which was at first thought to be related to the alleged anoxic contraction of the pulmonary *vessels exposed to low oxygen tensions*[9], *but* subsequent investigations showed that this reaction is not so simple as was at one time thought[10] retention of carbon dioxide may be more important in its pathogenesis than oxygen lack[11] For example, it was found impossible to lower the pulmonary arterial pressure in emphysematous patients by giving them oxygen to breathe[8] Improved understanding of these questions will be important to the rational management of chronic bronchitis and its complications

Another group of pulmonary hypertensions are those complicating lesions which usually give rise to left-to-right shunts, such as atrial septal defects, ventricular septal defects, and patent ductus arteriosus Increased pulmonary vascular resistance may develop in these conditions at any age A young child may have it though an elderly patient with the same disorder does not[12] Such random development has been thought to be due to some such accidental circumstance as persistence of the strong fœtal muscular coat of the lung vessels[13] Among a series of cases of unexplained pulmonary hypertension, **WADE** and **BALL**[14] reported one with abnormally narrowed muscular arteries in the lungs resembling those found in fœtal lungs They do not, however, consider that persistence of the fœtal form of vessels causes the hypertension, but rather that hypertension provokes this type of anatomical reaction New development of muscle in the arterioles of patients with mitral stenosis has been noted by **HEATH** and **WHITAKER**[15]

In Egypt, and possibly less commonly in other tropical areas, bilharzial eggs may reach the lungs as emboli, setting up an organising obstructive lesion[16] In peripheral venous thrombosis recurrent small emboli may do the same[17] In some cases of pulmonary hypertension related to pregnancy the cause seems to be small thrombotic emboli , and **WOOD**[3] emphasises that these patients, in whom the disease begins sub acutely, should be treated with anticoagulants **Harrison**[18] has shown that multiple small fibrin thrombi lodging in the lung vessels can cause pulmonary arteriosclerosis, but pulmonary hypertension was not consistently established in such experiments[19] The complication of pulmonary arterial embolism plagues the pathologist in his analysis of the lung vessels in all forms of heart-disease, including pulmonary hypertension Two of **Wade** and **Ball**'s cases were thus obscured, but the emboli could be identified as complications, for abnormally small arteries were found beyond them There may even be local thrombosis—often as a complication of embolism, but sometimes as a primary local process in the main trunks of the pulmonary arteries[20]

Rarely pulmonary hypertension may appear in collagen disorders such as scleroderma, dermatomyositis,[21] pulmonary polyarteritis, and possibly rheumatic arteritis[14] This ill-defined group leads us into the unexplained pulmonary hypertensions, on which several reports have lately appeared[22–24] This idiopathic disorder often appears in young women Dyspnœa is an invariable symptom, but orthopnœa has not been recorded except by **Evans** et al[23] Effort syncope is a notable feature, and a remarkable study by **Howarth** and **Lowe**[25] showed that this was due to a form of acute right ventricular failure **Wade** and **Ball** observed a death in one such attack Substernal pain on effort is common and hæmoptysis unusual There are signs of right ventricular hypertrophy with an accentuated second sound, and the electrocardiogram shows right ventricular preponderance The characteristic large venous "a" wave described by **Wood**[26] is an important physical sign Peripheral cyanosis is, for the most part, related to a low cardiac output, but reduced oxygen-saturation of the arterial blood is sometimes found, which **Wade** and **Ball** think may signify the development of arteriovenous shunts in the lungs In some cases **Evans** et al,[23] in fact, showed by injection methods collateral and anastomotic communications Radiologically the larger pulmonary arteries at the root of the lung are enlarged, but the distal branches are grossly narrowed Hilar dance is absent **Shepherd** et al[24] emphasise that inhalation of oxygen induces significant relaxation of the arterioles in the lung in congenital cardiac disorders with pulmonary hypertension This relaxation may be recognised by a significant increase in arterial oxygen-saturation It is not seen in primary pulmonary hypertension, and in this condition they found it impossible to measure the "wedge pressure" in the pulmonary capillaries —no doubt because of anatomical arterial obstruction

The study of pulmonary hypertension is one of the great new fields opened up by cardiac catheterisation New facts are still being accumulated rapidly Much has been learned but much more remains to be done Perhaps in a few years it will be possible to reach a better synthesis than seems possible today

The Anatomy of Memory

Abnormalities of memory, perhaps even more than those of perception, take doctors within the terrain of philosophy In some ways the difference between an object and its memory-image epitomise the problem of mind and matter Memory, in any wide sense, is concerned in all learning and the ability to make use of past experience, and all conditioning is an aspect of memory, which must be admitted very early in the phylogenetic scale In man the term commonly has a more precise and limited usage the conscious recall or recognition of past experience—a process suggesting far greater psychological and physiological complexity Normal memory is capricious, and the defects associated with cerebral disease are highly varied It has been recognised since the time of **Hippocrates** that injury and disease of the brain may produce defects of memory, but it is only in the past century that memory has been correlated with focal brain lesions In 1888 **Hughlings Jackson**[1] reported a case of epilepsy in which the aura comprised a dreamy state where things seemed familiar, as if they had happened before, clinical evidence suggested a lesion in the "temporo-sphenoidal lobe" Some ten years later **Jackson**[2] reviewed other such cases, in one of which necropsy showed a lesion in the left uncinate gyrus Since then "uncinate fits," with a *deja vu* aura, have generally been considered to reflect discharge from the medial temporal region

Scoville and **Milner**[3] have now described 8 cases in which bilateral removal of the anterior part of the medial temporal lobe, including the uncus and hippocampus but leaving the lateral temporal cortex intact, permanently impaired memory for recent events The resections were made blindly through frontal trephine holes, and some were combined with orbital undercutting, but it is reasonable to suppose that the damage was in fact mainly in the antero medial aspects of the temporal lobes The memory defect was essentially one of "memorising," and there was no evident loss of preoperative memories or of intellectual ability Such findings seem to be the obverse of **Jackson**'s "discharging" lesions with their sense of diffuse reminiscence, but the precise rôle of the uncus remains in doubt, since in a further case, where the bilateral ablation included the uncus but fell short of the hippocampus, the memory defect was not noted Necropsies in Korsakow's amnesic syndrome (where the characteristic picture is gross loss of memorising combined with confabulation or pseudo-reminiscence to fill in the memory gaps) have shown maximal damage in the hypothalamic region and especially the mamillary bodies This is found not only in alcoholic cases but also when the syndrome is caused by cerebral neoplasm Thus two distinct anatomical sites seem to be involved in laying down memories, but they do not necessarily represent two disparate mechanisms, since the hippocampus projects by way of the fornix very largely on to the mamillary bodies, thus providing an anatomical basis for functional entity

These observations throw light on the process of memorising, but do not touch directly on the problem

of specific memories or what a past generation would have termed ' memory engrams ' Information on this is being provided by the study of epilepsy and its surgical treatment Occasionally the aura of epilepsy involves a memory, either visual or auditory, or both In some such cases **Penfield**[4] has located the epileptic discharge in the posterior temporal region of the dominant hemisphere He has elicited the visual and auditory "memory" by electrical stimulation of the cortex and occasionally the memory was not a static isolated affair but showed something of the normal march of naturally recalled happenings In a study of epilepsy following focal brain wounds **Russell** and **Whitty**[5] recorded cases of occipito-parietal and occipito-temporal wounds where specific remembered scenes arose as a visual aura In one case the memory aura was more complete and involved the re-experiencing of a past event including the sights, sounds and emotional content of the original situation. In such cases we see the storehouse of memory being artificially opened and the sites involved seem to be widespread in the posterior temporal temporo-occipital and even posterior parietal cortex. But the relation between the function of such areas and individual memories is certainly not a simple one It is impossible to say that this or that memory is contained in this or that area of cortex ; for if the cortex is excised the memory is often largely unaffected. Even in the sphere of word-memory where we can say with some certainty that excision of one area of cortex will produce an amnesic aphasia the correlation is far from precise What the excision brings about is not loss of the memory of a number of words but rather loss of memory of a diffuse skill in the use of symbols in which a surprisingly variable loss of individual word-memory is included. Indeed to think of memories in terms of locality may be to search for a chimæra for every memory must contain something that is the function of many (perhaps all) cortical areas—visual, auditory, motor, and sensory Nevertheless the evidence enables us to picture a mechanism with a subcortical and cortical substrate concerned in memorising: a mechanism which invokes the cortex to supply the specific content of individual memories

Annotations

VIROLOGY AT GLASGOW

Glasgow University is to have a department and chair of virology the first of their kind in Britain[1] The department which is to be beside the main university site at Gilmorehill is expected to open in or about 1960. The Scottish Hospital Endowments Research Trust has given £225,000 to cover the cost of construction and equipment (estimated at £200 000) and the initial running costs. The Medical Research Council is to attach a research unit to the department. Dr. J. W Howie professor of bacteriology in the university, said last week that some fundamental research in human virology is being done in Great Britain but not nearly enough because our material resources for such work do not compare favourably with those overseas—notably in the U S A and Australia Professor Howie expressed his confidence that the new department will at least equal anything in existence elsewhere "We are hoping,' he declared. to establish a centre that will attract researchers from all parts of the world "

THE GROUP TEACHES ITSELF

Methods of teaching undergraduates are a perpetual source of argument, Lectures tutorials textbooks—all have their champions and detractors Prof J M Mackintosh[2] describes an interesting method used in postgraduate teaching in the department of public health at the London School of Hygiene and Tropical Medicine in which groups of students study some particular questions and present a report on each

Before the beginning of the academic year members of the teaching staff meet and discuss possible topics and 6 to 8 projects are decided on about the end of October Each is briefly described on the students' note-board The students state their preferences and are then allocated to study groups Each group has one tutor and about a dozen students—chiefly those taking the D P.H course with one or two qualified nurses and perhaps a psychologist. Many of the students have come from overseas In the first few meetings of a group its members get to know each other and appoint a chairman and secretary. By the end of term a provisional programme has been arranged ; some students will be keenly interested some hostile, some apathetic By the beginning of the Spring term some work will have been done and some proposals abandoned. There is usually a period of frustration when disappointments are met with, the members disagree, students from tropical countries feel the cold of a London winter, and the pressure of other work becomes distracting But the enthusiasm of a few members usually keeps the group going, and the camaraderie of the group may be helpful to the lonely visitor from abroad

Gradually the material accumulates The group may split up For instance, the men of action may prefer to go afield to interview, to examine, and to collect facts, while the men of thought plan the campaign sort the evidence and analyse it The chairman can be valuable in this reconciling opposing temperaments. The next stage is to decide on presentation Possible schemes include a series of short reports with linking remarks by the chairman , a dramatic presentation : or film strips and exhibitions Some groups prefer a statistical, some a descriptive, approach The last few days are marked by alternating enthusiasm and despair, till the great day when the presentation is made.

Many advantages are evident in this scheme The students of a group have the opportunity of making friends and of working as a team Excessive classroom teaching is avoided The project is an exercise in method ; for example much more is learned by actually planning and carrying out a social survey using a questionary than by hearing lectures about it Statistical methods are seen in action in the analysis of real material and not just as an academic exercise Finally, the presentation gives valuable training in health instruction and propaganda which is a very important part of public-health work.

The topics dealt with by study-groups in 1955–56 included an exhibition showing the development of health services and the work of medical officers of health through the hundred years since their society was founded , studies of the common lodging-houses in London, of the little markets, of the work of the National Assistance Board, of a railway terminus and of the questionaries sent to parents before school medical examinations and a discussion of many aspects of health education

CONTRACEPTION IN CHINA

THE Chinese People's Government is reported to have reversed its policy on family planning and contraception Previously, like most other Communist governments, it had been bitterly hostile to such practices, but the change is not unexpected The infant death rate in China is reported to have fallen by 2,000,000 a year, and in any case contraception by various methods (including abortion) is already a *fait accompli* a government newspaper recently *put the proportion of women workers* and clerks who have used contraceptive appliances or traditional herbs at 70% (This probably refers to the urban public, but figures in the villages may not be much lower) Accordingly a campaign to disseminate information on contraception is to be undertaken such campaigns, on other topics, have been prosecuted with enormous energy, and have proved highly effective in teaching simple hygiene At the same time abortion is legalised—chiefly to bring it under supervision—but not specifically encouraged

There is little to surprise us in the change of front—what will be really interesting will be to see exactly what methods of contraception are to be taught The mechano chemical methods used in the West are effective and more or less adequate under urban conditions, but experience in India has already shown that for rural populations, especially those which have climatic and literacy problems and live under simple conditions, they are quite unsuitable Research on fundamentally new methods is at present scanty While government planners might be quite content with any method which merely reduced the overall birth-rate, individuals will not be so easily satisfied They will expect a reasonable measure of certainty in action, and one or two notorious failures may, very reasonably, determine the future attitude of a whole village to further instruction of this kind Given some measure of reliability the demand for instruction is no doubt enormous There may be traditional opposition in China to any restriction of fertility, but the influence of the old economic and religious significance of fecundity and posterity must be very heavily offset by the demand of the newly emancipated generation of Chinese women for relief from continuous compulsory pregnancy

The best approach for the organisers of contraceptive education in the villages will probably prove to be the advocacy of a simple female occlusive method, possibly combined with the sheath and the "safe period"—any two of these would probably effect a substantial reduction in the incidence of pregnancy Tampons of paper or other materials are the basis of most of the effective folk methods—male appliances are certainly familiar in the towns, but the sheath as such might conceivably arouse opposition based on a long standing belief in Chinese medicine that the male absorbs virtue from the female secretions

Few Western observers would probably now advocate the "safe period" alone as a contraceptive method in any community where it was not preferred for religious or similar reasons But it might be worth seeking other behavioural methods of reducing fertility the results of research on infertility, carried out with the opposite *intention, already suggest* that such an approach is possible There are, for example, individuals who can keep their sperm count below the fertile level by maintaining a high frequency of ejaculation, and it seems likely that some couples could live a relatively or wholly infertile sexual life by adjusting their coital habits But owing to the enormous range of individual variation in fertility and capacity, this method would require careful individual laboratory study and failures would be frequent even in countries with expert fertility clinics A cheap mechanochemical method is probably the only effective contraceptive which could be promoted on a national scale by a Communist type education drive Our failure so far to find a relatively simple biological o pharmacological contraceptive is partly the result of our ignorance of the actual mechanics and pattern of human coital behaviour The adoption by the Chinese Communists of a positive attitude towards contraception may very well lead, for practical reasons, to the revision o another doctrine—that which condemns the study o human sexual ethology If so, it will be yet anothe instance where practical needs exert the same compulsio on the attitudes of societies as different *as our own, th* American, and the neo-Chinese

CONSERVATIVE MANAGEMENT OF URETERIC CALCULI

IT is often difficult to decide whether a ureteric ston will be passed spontaneously *Gartman*[1] *points out tha* surgical treatment has been found necessary in proportions of cases ranging from 7% to 54%, and h suggests *that* the figures at the upper end of this scal relate largely to cases sent for specialist advice on accoun of resistance or chronicity In the U S Armed Force all cases of ureteric calculus are referred at the outset t a urologist In 218 consecutive military cases referre to him, Gartman applied expectant treatment wheneve practicable Of 237 ureteric stones (in the 218 patients) 186 (78 5%) were passed spontaneously without complications, 38 were dealt with instrumentally, and onl 13 (5 5%) had to be removed by ureterolithotomy

Undoubtedly these figures reflect fairly the likelihood of natural passage, but some qualification is necessary in applying them to civilian practice Interference with business or other urgent activities by recurrent symptoms sometimes influences the decision when to interven Moreover in the general population there will always be a few with renal insufficiency in whom the removal o a stone is a matter of urgency Gartman's account i important because it provides some idea of the prospect of spontaneous cure in uncomplicated cases

PERFORMANCE IN PRACTICE

AN attempt has now been made to assess the performance of general practice in an American State by combining observation with use of the statistical method Of 102 representative general practitioners in North Carolina whose cooperation was sought, 94 agreed to allow their methods of work to be observed by two observers from the programme planning section of the Division of Health Affairs of the University of North Carolina These observers visited each practice separately, "sitting in" on each doctor for a few days at a time, *sometimes revisiting at a different season*, and so ordering their journeys from practice to practice as to eliminate statistical error where possible Considerable pains *had been taken to study the range of difference* in observations between the observers and also the within observer error arising in the interval between observations The great care in *allowing* for such *errors* as this gives authority to the results

The performance of the doctors was measured in two ways One observer awarded *an* ordinal grading from I up to V (mediocre to outstanding) which could be statistically matched to a quantitative numerical score This score was obtained by *allotting* "weights" to different aspects of the diagnostic and therapeutic processes examined Emphasis was placed on the diagnostic process in internal medicine, such qualities as surgical or obstetric technique being expressly excluded When the ordinal and numerical rankings were found to be statistically comparable, attempts were made to see how and why the doctors distributed themselves within the gradings as they did Little was overlooked from performance in medical school to age, type of

---

1 Gartman E *U S Armed Forces med J* 1957, 8, 313

2 Peterson, O L Andrews L P Spain R S, Greenberg B G *J med Educ* 1956 31, no 12, part 2

practice, previous hospital experience—all the factors which must contribute to the performance of the doctor in Cheltenham as well as North Carolina—and the figures show much that was expected as well as much that is new

The evidence shows that the better medical students become the better practitioners, and that clinical merit cannot be directly related to the number of patients cared for nor, even under conditions of private practice, does it appear that the best doctor achieves the highest income Opportunities for postgraduate education were neglected by doctors in the lower groups In some practices both history taking and examination showed little clinical knowledge or skill, and one of the objects of the study was to identify the fundamental reasons for this

Though the conclusions of this report are valuable they may not be applicable under different conditions of practice elsewhere, and the main merit of the work lies in the methods of investigation Clearly the observer of general practice should be detached from it yet experienced in it, and when he is joined by a statistician scientific appraisal is feasible Studies of this sort should be encouraged wherever there are standards of general practice to be improved—and this means wherever there are doctors in general practice

CORTISONE AND IMMUNITY IN TUBERCULOSIS

CORTISONE or related drugs are now administered to tuberculous patients with less hesitation than in the past The indications for the use of these drugs in tuberculosis are now said to include obstructive lesions due to adhesions, stress,[1] exhaustion after major operations,[2] and hypersensitivity[3], and simultaneous administration of antimicrobial drugs is believed to deal adequately with the tubercle bacillus But opinions on the advisability of cortisone therapy for patients with pulmonary cavities are still conflicting

Cortisone aggravates tuberculosis in mice,[4] and cortisone and corticotrophin diminish tuberculin sensitivity in guineapigs previously sensitised with B C G [5–7] From this it might be inferred that these agents lower resistance and hence promote spread of tuberculous infection, but guineapigs which have been vaccinated with B C G apparently suffer no impairment of acquired immunity through administration of cortisone before being infected with virulent tubercle bacilli[8]

Light has lately been thrown on the cellular response to tubercle bacilli in animals receiving cortisone Pagel and Treip[9] injected heat killed tubercle bacilli intradermally into guineapigs which had been sensitised by a previous injection of bacilli of the same type During the period of developing sensitivity one group was treated with cortisone and a second (equally sensitised) group was left without cortisone and served as controls In all animals the first injection was followed by the usual sequence of histological events

> By the sixth day an abscess replete with tubercle bacilli had formed, from about the sixteenth day the abscess was gradually replaced by a tuberculoid granuloma consisting of large macrophages and many giant cells filled with acid fast rods Bacillary disposal was not complete until the sixth or seventh week, when only acid fast dust remained

After the second injection in the controls, the process was much faster on the sixth day a granuloma was present and tubercle bacilli were no longer visible, and the histological picture resembled that at the fiftieth day after the sensitising injection In the cortisone-treated animals disposal of tubercle bacilli was hardly less rapid than in the controls, but the histological picture differed conspicuously mononuclear, epithelioid, and giant cells had taken no part in removing the bacilli, which had all perished virtually in the abscess itself, suggesting a humoral rather than a cellular mechanism

These interesting findings are consistent with the observations of Long and Miles[5] on the depressant effect of cortisone on tuberculin sensitivity cortisone apparently reduces the cellular response without preventing (though it slightly delays) disposal of tubercle bacilli[9] These findings also explain the lack of interference by cortisone with the efficacy of B C G vaccination In short, cortisone does not seem to impair acquired resistance in guineapigs This encouraging revelation surely invites experimental study of its effect under conditions of natural resistance

EPITHELIAL HYPERPLASIA IN THE LUNGS

MUCH attention is being paid to areas of epithelial hyperplasia forming small nodules, almost like tumours, in the lung parenchyma in relation to terminal bronchioles and alveoli The cells in the nodule may be tall columnar with or without mucous secretion or cilia,[10 11] cuboidal, or flattened[12], but often they are small and oval,[13–16] reminiscent of the oat cell carcinoma or carcinoid tumours of the appendix, though without argentaffin granules in the cells Rarely, the cells show squamous characters[16] The cells may be seen in clusters of acini round terminal bronchioles, or they may line alveoli or form masses filling alveoli The main points of interest about these cells are the conditions in which they are found and whether or not they are to be regarded as precancerous, either for bronchial carcinoma or for alveolar cell carcinoma

So far, it is not claimed that the condition is common Whitwell[15] examined 2300 surgical specimens of lung (including 900 resected for bronchiectasis, 600 for tuberculosis, 500 for carcinoma, and 80 for abscess) and 1400 necropsy specimens, and found these nodules in 24 cases (22 surgical) The sex-distribution of the material was roughly equal, but in 18 of the 24 affected cases the patient was female The nodules were multiple in three-quarters of the cases and developed from bronchi, bronchioles, alveoli, or even pleura Whitwell claimed to see hyperplastic cells in dilated bronchial and pulmonary lymphatics (King[16] points out that the identification of lymphatics in these nodules is very difficult), but he could find no extension to lymph glands in the 15 specimens which could be examined for this He remarks that these islets of hyperplasia are a serious trap in sputum cytology and may account for the occasional false positive reports of malignancy, especially in cases of bronchiectasis He found such nodules almost exclusively in cases of bronchiectasis or chronic abscess, they bore no relation to the occurrence or distribution of carcinoma of the bronchus Spencer and Raeburn[14] and King[16] hold that most of these nodules are innocent proliferations of bronchiolar epithelium related to non-specific inflammatory or fibrotic lesions in the lungs They are thought to be becoming commoner partly because of the increase of viral and atypical pneumonia which heals by fibrosis rather than by resolution, and partly because organisation of exudate and subsequent fibrosis often follow the administration of antibiotics[17] in bacterial pneumonias These proliferations have not so far been associated with tuberculosis [18]

The presence of a few mitotic figures and some local extension of the hyperplastic cells by natural passages are compatible with simple hyperplasia, but in some cases definite carcinoma of the terminal bronchioles or alveolar epithelium has been identified by secondary spread—e g, to hilar glands [19, 20] This diagnosis should be accepted, however, only if there is no demonstrable carcinoma elsewhere,[10, 11] either at necropsy or for some time (e g, five years) after operation In particular, there must be no small primary growth higher up the bronchial tree,[21] especially where there appear to be multiple primary foci in the periphery of the lungs, and where there is extensive mucoid spread throughout one or more lobes [22] In another type of primary growth, described as pulmonary adenomatosis,[23] a peripheral mass spreads by many small outgrowths, causing progressive involvement of large areas of the lung, this does not seem to be related to the nodules of epithelial hyperplasia following scarring of the lung, but it confuses the *nomenclature*

Rare disorders have an extraordinary propensity for coming in small runs There are many reports [11, 18, 19] of series composed of a few cases with these nodules of apparently simple hyperplasia and a smaller number of cases with superimposed malignant changes, and there is a tendency to assume that the simple hyperplasia is inevitably followed by malignancy Then comes the assumption that the epithelial hyperplasia, bronchiolar or pulmonary adenomatosis, and alveolar-cell or bronchiolar carcinoma are phases of a single process [24, 25] From this, it is taken as proved that the sex-distribution of carcinoma of the alveolus (almost equal in males and females, or even commoner in females) is very different from that of carcinoma of the bronchus (about 5 males to 1 female) But it must be realised that many of these so-called carcinomas of the lung alveoli or of the bronchioles were originally reported as areas of hyperplasia and were not proved or claimed to be malignant even some claimed originally to be malignant [26] might not now be so classified in view of the later reported series [14, 15] Further, several cases of true alveolar carcinoma have been reported in series of bronchial carcinomas with strong male predominance [22, 27], and if these were added to the cases reported separately the sex-distribution would be very different Spencer and Raeburn [11] recognise the reported equality in sex-distribution but point out that 5 of their 6 cases were in males so also were the cases with extrapulmonary spread in Beaver and Shapiro's series [18]

Similar reasoning is used to show that cancer in the alveoli is due to chronic inflammation [11, 17] It has long been known that epithelial hyperplasia arises at the edges of chronic infections or sites of irritation—e g, in skin ulcers, gastric ulcers, and erosions of the cervix—but that this change is rarely supplanted by true malignancy Now that lung pathology is receiving increased attention vis-a-vis cancer, surely the same caution must be exercised here, and it may well be shown in the future that other agents besides infection are needed to induce the actual malignant change—perhaps the same agents as in bronchi Auerbach et al [28] have shown that, in the mucosa of the trachea and bronchi, areas of basal cell hyperplasia, stratification, squamous metaplasia, and even "carcinoma in-situ" are seen in unexpected numbers, certainly more commonly in smokers, but even in non-smokers who die from causes other than carcinoma of the lung, and these changes are found even in the trachea, in which carcinoma is very rare

At present it seems advisable to restrict the names used as far as possible—reserving pulmonary adenomatosis for the condition described by Hutchison and Fraser,[23] and pulmonary adenoma (simple or multiple) for true simple tumours [29], the term epithelial hyperplasia nodular or diffuse, should be used for the effects of chronic inflammation or fibrosis Exacting criteria should be fulfilled before carcinoma of the alveoli or terminal bronchioles is diagnosed

HARVEY'S TERCENTENARY

William Harvey died on June 3, 1657, and the tercentenary of his death will be commemorated next month in London by the Royal College of Physicians and the Harveian Society and by many distinguished guests from abroad On June 3 at 9 30 A M at the Royal College of Surgeons, Lincoln's Inn Fields, W C 2, Mr A Dickson Wright, the president of the Harveian Society, will open an international congress on the circulation of the blood, and on the same day at noon the Royal College of Physicians will hold a memorial service at St Paul's Cathedral The congress will continue in London till June 7, and the speakers will include Prof C Heymans (Ghent), Prof Gustav Nylin (Stockholm), Dr Donald E Gregg (Washington), Dr Claude S Beck (Cleveland, Ohio), Dr Andre Cournand (New York), Dr S Radner (Lund), Prof G d'Allaines (Paris), Dr Seymour S Kety (Bethesda, Maryland), Prof T Alajouanine (Paris) Dr Stanley E Bradley (New York), Dr J F Fulton (Yale), Dr F A Wilkins (Mayo Clinic), Dr L W Katz (Chicago), Dr S Weidmann (Berne), Prof K Matthes (Heidelberg), Prof A D Volta (Padua), and Dr Louis Chauvois (Paris) Sir Russell Brain will give the concluding address in London at 2 P M on June 7 On June 8 the congress will hold a historical meeting, under the chairmanship of Sir Geoffrey Keynes, in Folkestone which was Harvey's birthplace There will be a service at Canterbury Cathedral in the afternoon

During the congress an exhibition will be held in the library of the Royal College of Physicians, Pall Mall East, S W 1, to illustrate Harvey's life and work It will include his demonstrating rod, his diploma, the drawing of his Stemma, letters, and the earliest extant Harveian oration (by Edmund Wilson in 1658) A new translation of *De Motu Cordis* by Prof K J Franklin, F R S, has been sponsored by the college A new edition has also been made of the black and white silent film prepared in 1928 by Sir Henry Dale, F R S, and the late Sir Thomas Lewis to illustrate some of Harvey's most important experiments The 1957 version, for which a grant was given by the Wellcome Trustees and which has been made by the Wellcome Film Unit, uses colour, animated diagrams, and a sound-track Happily it retains Sir Henry Dale as one of its stars and he contributes an introduction From June 3 to 7 the film will be shown daily at the college at 5 P M and 5 45 P M

During the week of the congress a Harvey exhibition will also be on view at the Wellcome Historical Medical Library, Euston Road, N W 1 Later in the month, on Sunday the 23rd, at 3 P M, there will be a commemoration service at Hempstead Parish Church, Essex, where Harvey is buried

INFLUENZA BETWEEN EPIDEMICS

A SEROLOGICAL STUDY

P N Meenan

From the W H O Influenza Centre, University College, Dublin

Our knowledge of the attributes of the influenza virus is now very detailed, but there are many gaps in our knowledge of the relationship between it and its host Not unnaturally, most investigations of this have been made during epidemics, and, owing mainly to the difficulty of recognising the disease clinically and so distinguishing it from many other acute respiratory infections, we are comparatively ignorant of the position which obtains between epidemics Relatively few studies aimed at elucidating these problems have been reported, the most important are those of Hoyle and Fairbrother (1947) and of Stuart Harris et al (1954)

The present investigation was initiated by the recovery of influenza-A virus from two localised outbreaks in the vicinity of Dublin in May, 1954 In view of the possibility of an autumn epidemic following these outbreaks (Isaacs and Andrewes 1951) it seemed that an opportunity might have arisen to study the genesis of such an epidemic, using the complement-fixation test, and particularly to see whether silent seeding of the virus throughout the population could be detected before it In the event, no autumn epidemic occurred, but the study continued from June, 1954, to August, 1955 during which time an outbreak due to influenza B and yet another due to influenza A were recorded, in January, 1955, and March, 1955, respectively The viruses responsible were isolated in each case The 1955 influenza-A strains were antigenically distinct from those of 1954, being the prototypes of the Eire '55 strains which were isolated almost simultaneously in this country, Great Britain Albany, N Y and India (Isaacs 1956) We were able therefore, to investigate the population concerned before, during and after those periods at which virus was known to be circulating

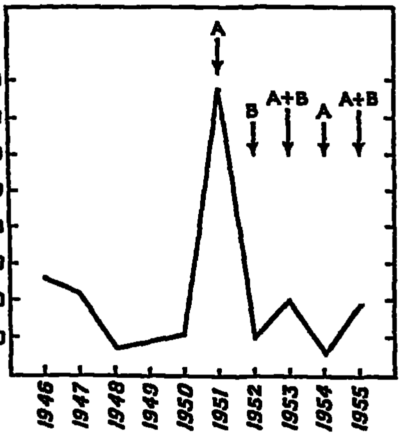

Fig 1—Mortality rates and viruses isolated

As it has been suggested that antibodies demonstrated by the complement fixation test between epidemics may derive from infection in a previous epidemic, the background to this study is shown in fig 1, which records the mortality rates and the viruses isolated in this country in recent years It should be noted that, except for 1951, when a severe epidemic with a high mortality occurred early in the year (Meenan and Clarke 1951) the recent isolations were from localised outbreaks, and there was no subsequent large epidemic By June, 1954, therefore more than three years had elapsed since the previous epidemic of influenza A, the most recent epidemic of influenza B had probably been in 1946 In our experience localised outbreaks were as likely to have been due to A viruses as to B

Materials and Methods

During the period of the study 5084 sera were examined by the complement-fixation test for antibodies to influenza A and B

Except for a few specimens received for the Wassermann reaction, the sera were all obtained through the National Blood Transfusion Service from donors with no history of recent illness They were collected locally in different parts of the country by teams from Dublin, which meant that the areas more remote from Dublin were visited only at intervals, and a continuous sample was not obtained from them During December and January the vast majority of the specimens received were from Dublin The specimens examined could, however, be taken as representing a fair cross section of a healthy portion of the adult population at the time they were collected.

The sera were examined at an initial dilution of 1 8, and those positive at this dilution were further titrated For the purposes of the investigation a positive result at 1 8 dilution was regarded as significant and recorded as positive In patients with an illness of the respiratory tract a titre of 1 16 in a convalescent specimen examined by the complement-fixation test is taken as pathognomonic of influenza Our specimens were collected from a sample of the general population who, as blood-donors, could be presumed to be in good health, and our interest was in possible subclinical infection rather than in known convalescents For these reasons a titre of 1 8 was regarded as significant, being not so high as to detect only frank cases yet high enough to ensure that positive results of doubtful significance at low dilutions of serum could be eliminated

Complement-fixation Test—The method used was that recommended by an expert committee of the World Health Organisation (1953) as regards both the preparation of antigens and the technique of the test Soluble antigens prepared in fertile eggs from PR8 and Lee strains were used throughout

Sera were stored at –15°C where necessary before examination As only a few sera were collected in August and September, 1954, the results for these two months were pooled No sera were collected in June, 1955

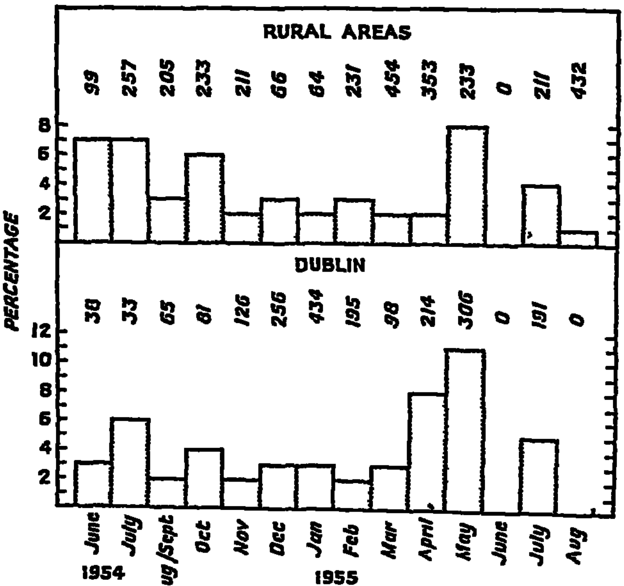

Fig 2—Results of complement-fixation tests for antibodies to influenza A virus

Results

The results for influenza A and B are shown in figs 2 and 3 respectively They are broken down into those for Dublin city and county on the east coast, which is predominantly urban, and those for the rural areas The former, with a population of just under 700,000 in an area of 350 sq miles, contain almost a quarter of the total population of the country The rural areas consist of most of the rest of the country except the south-western region, which is not visited by the National Blood Transfusion Service A very few specimens sent from this area for the Wassermann reaction are included The exclusion of this region means that the rural population investigated numbered about 1,200,000 persons living in a countryside containing only eight towns with populations over 10,000, the largest having 30,000 inhabitants, in an area of about 12,000 sq miles As might be expected, the rather more thickly populated eastern counties within easier reach of Dublin were more intensively sampled than the very thinly peopled western seaboard, but in the results these rural areas showed no great differences between them

The findings for influenza A show two periods of activity One, during the summer and autumn months of 1954, affects the rural areas to a rather greater extent than Dublin This suggests that the viruses isolated near Dublin in May of that year may have spread slowly outwards from Dublin, for the proportion of positive sera was highest in the west during October, when the level had fallen to negligible proportions in the rural areas in the east During the winter months only very slight activity due to influenza A was detected serologically anywhere in the country before it became epidemiologically evident in Dublin during March with the appearance of the Eire 1955 strains there This is reflected in a rise in the number of positive sera found in April, which again increased in May and was still above the winter level in July This rise occurred a month later in the rural areas, although apparently not to the same extent, and appears to have been confined to the eastern part of the country As no specimens were collected in June, it is impossible to be dogmatic on this point, but a large batch of sera from the midlands in August showed less than 1% of positives

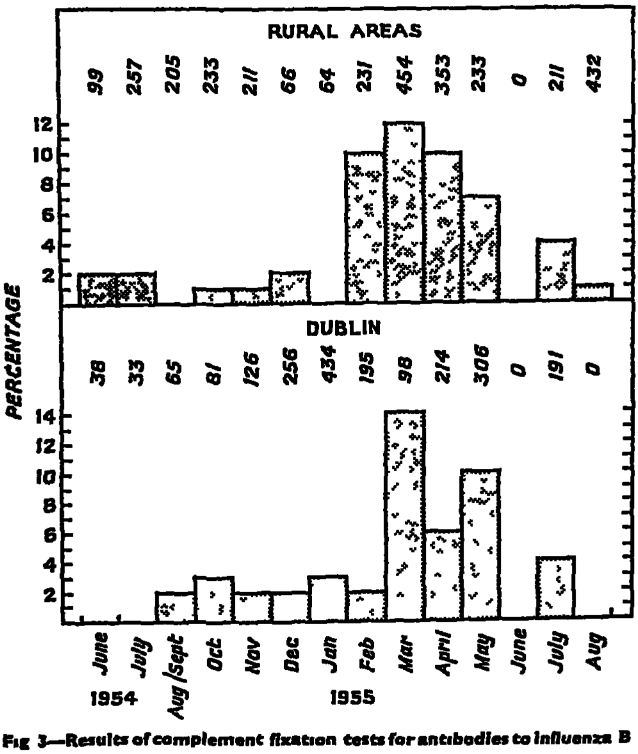

Fig 3—Results of complement fixation tests for antibodies to influenza B virus

Neither in 1954 nor in 1955 did influenza A appear to be frankly epidemic in Dublin or throughout the country Nevertheless the serological results show a fairly sharp increase following the period when influenza virus A was circulating in Dublin in March, 1955, and there is no suggestion of any earlier widespread dissemination of virus such as might happen during a period of "seeding" before an outbreak

The findings in respect of influenza B seem clear cut After months of predominantly negative results there was a sharp rise in all the areas early in 1955 which, in the rural areas at least, had completely died away six months later In Dublin the rise in the number of positive sera took place two months after the epidemic of influenza B The peculiar fall in April may have been due to a sampling defect in either March or April, but it may serve to emphasise that the population from which the specimens were drawn was predominantly healthy The main brunt of the January epidemic appeared to fall on school children rather than on adults, and most schools were closed during the latter part of the month, having opened in the ordinary way after the Christmas holidays

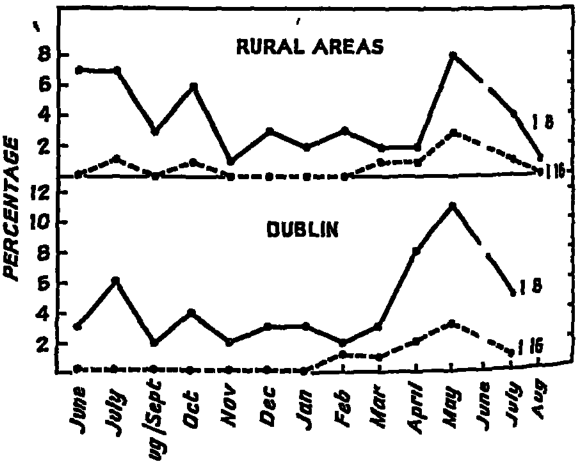

Fig 4—Proportion of sera positive for influenza A at a dilution of 1 16 or higher

The rise is shown in the rural areas a month earlier than in Dublin, this being almost entirely due to the findings in the area north of the city, which, however, was inadequately sampled in the immediately preceding months, and one cannot say whether or not the epidemic may have originated there In any event all the rural areas rapidly became involved, and it is clear that they suffered severely Again one may note (and it is even more conspicuous in this instance) the apparent lack of any build up before the epidemic

Figs 4 and 5 show the proportion of positive sera which, on subsequent titration, were positive at a dilution of 1 16 or higher The two curves parallel each other closely and, for the period covered in 1955, the curve of the 1 16 dilution supports the epidemiological findings Its significance during 1954 is less obvious, except perhaps to suggest that influenza A was slightly more active in the rural areas than in Dublin in the autumn of that year

Discussion

One of the difficulties in a study such as this is to define the proportion of positive sera which one might expect to find during interepidemic periods Stuart Harris et al (1954), working at a serum dilution of 1 4, found 5–9% of positives for influenza A as against 20–30%

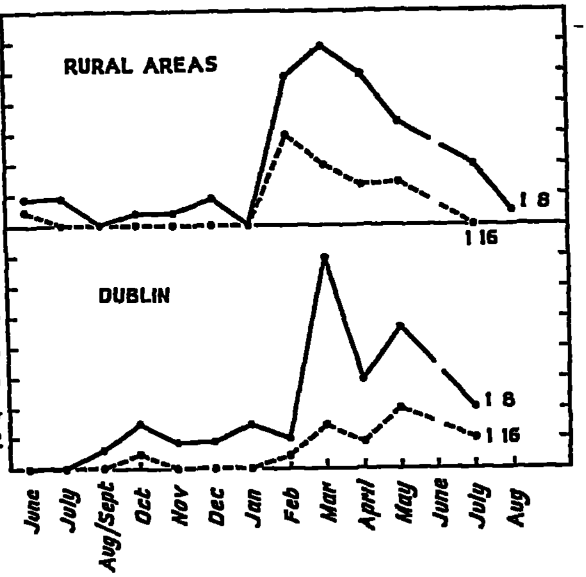

Fig 5—Proportion of sera positive for influenza B at a dilution of 1 16 or higher

found by earlier workers They suggest that their lower levels may have been due either to a real alteration in antibody levels following the introduction of the A-prime viruses or to technical differences Hoyle and Fairbrother's (1947) report shows 7% of positives for influenza A and 4% for influenza B at a dilution of 1 8 and over in inter-epidemic periods Our findings suggest that the corresponding figure in our series is at most 2–3% and may well be less In essentials the technique used in this investigation is the same as theirs, except that the antigens were prepared in fertile eggs instead of mouse lung There is some evidence that the A-prime and subsequent viruses may give rise to a poorer antigenic response than did the earlier A strains, but this change does not, so far as we know, hold for influenza B, hence, though the lower figures obtained by Stuart Harris et al (1954) and, to a much lesser extent, by ourselves might be due to the preparation of the antigens in the fertile egg instead of mouse lung, they could also have been due to differences in antibody levels with recent A strains

If the figure of 2–3% in this series represents a normal finding, it appears that there was no evidence of pre-epidemic seeding in Ireland during 1954–55 before outbreaks of either influenza A or B, but that in each case infection erupted suddenly after a period of minimal detectable activity Evidence for such pre epidemic seeding would be exceedingly difficult to obtain except by serological means, and in this series the evidence suggests that at least it is not necessary for it to occur Similarly, it seems that the methods used in this study would be valueless for forecasting an epidemic, for the rise in the proportion of positive sera lagged behind the epidemiological findings

On the other hand, our results show that almost all evidence of an outbreak, as detected by complement-fixation tests on random samples, may have disappeared by the end of some six months afterwards This being so, it seems improbable that even the low level of 2–3% of positive sera could derive solely from persons infected during a previous epidemic some years before It is more likely that at least a proportion of these positive sera reflect constant low grade activity of virus circulating " underground " in a population essentially immune to it The origin of an epidemic would then depend on the appearance of a new strain of virus, arising either locally or by importation and with sufficient capacity to spread, rather than on a decline of the immunity level of the population and the recrudescence of a pre existing strain The data presented here, however, cast little light on how such a new virus might appear, for one did arise during this study, but the methods used give no clue to its origin Nevertheless it would be reasonable to expect such a new virus to emerge at a time when the population is immune to earlier strains Its subsequent history—as a major problem or as a curiosity—would depend on many factors, of which its own antigenic novelty and capacity for spread are only two

Summary

Between June, 1954, and August, 1955, 5084 sera, almost entirely from healthy blood-transfusion donors, were examined by the complement-fixation test for antibodies to both influenza A and influenza B

Two outbreaks—one of influenza A and one of influenza B—occurred during the period of study Each is reflected in a rise in the antibody content of the sera collected subsequently The pre epidemic level is reached again at the end of about six months, and a few positive sera detected between epidemics probably reflect current low-grade virus activity

No evidence was detected of seeding of virus in the community before the outbreaks, and both outbreaks occurred after periods of minimal activity as reflected by serological tests

This study was carried out with the aid of a grant from the Medical Research Council of Ireland, and Dr Clarke is a Fellow of the Council Our best thanks are due to Dr J P O'Riordan, medical director, National Blood Transfusion Service, for supplying almost all the specimens tested The patients from whom viruses were isolated during the outbreaks were kindly reported to us by Dr W R F Collis, Dr E M Caraher, Dr S McCann, Dr J F Fleetwood Dr C J O'Sullivan, and Dr V J Doyle

Joint Tuberculosis Council

At a meeting on March 1, the council strongly supported the views expressed in a report by its radiological committee—namely, that much more extensive use should be made of mass radiography In industry both employers and employees should (in their own interest) arrange for pre-employment radiographs For the protection of the public, annual radiographs should be required of workers in public transport and the catering trades

The report recommends improvement of the present mass-radiography service by providing miniature X-ray units in all chest clinics for the examination of persons referred by general practitioners, and of others who wish it The extension of the service in this way would make chest radiography easily available to everyone, and pre-employment films could be provided either by the chest-clinic service or by private arrangement with industry

First Quarter in England and Wales

The Registrar-General has announced[1] provisional figures for the first quarter of 1957 in England and Wales Live births numbered 183,676, or 16 7 per 1000 population The corresponding rate last year was 16 2 There were 134,621 deaths registered—a rate of 12 2 per 1000 population, compared with a rate of 15 3 in 1956 and 13 6 in 1938 in the corresponding quarters The infant-mortality rate was 25 0 per 1000 related live births in 1938 the corresponding figure was 69 3

CARE OF CHILDREN IN HOSPITAL

Report from the College of Physicians

FOR the guidance of individuals and authorities who are planning the care of children in hospital, the pædiatric committee of the Royal College of Physicians of London have recorded their views on this important subject Their report, which does not deal with the care of mentally defective children, was accepted by the college in comitia last week We reproduce the text in full

General Considerations

The proper care of children in hospital is so different from that of adults that their admission to adult wards is to be deprecated It is realised that such admissions may sometimes be necessary to obtain investigation and treatment in specialised units, but when this occurs there is a particular need for close liaison with the pædiatric services

There is no doubt that special children's hospitals offer the best service for children, because the staff, at all levels and in all departments, is attuned to the special needs of the sick child Children's hospitals carry with them a tradition of service which cannot lightly be set aside

In large general hospitals a separate self-contained children's block in close association with the obstetric department of the general hospital is desirable Where there is no separate children's block all children should be in special wards in a single unit under the general supervision of a pædiatrician, with a sister in charge who has had training and experience in nursing sick children A children's unit makes possible such amenities as schooling and facilities for play, &c It is most desirable, as suggested by the Ministry of Health (R H B 48 1) that the consultant pædiatricians of outlying units should, where possible, be connected with central units so that they do not work in isolation

Psychological Needs

The psychological aspects of childhood illness are increasingly recognised, not only in the field of psychosomatic illness, but also in the appreciation of psychological difficulties arising from physical illness and from hospitalisation To prevent these it is recommended that, whenever possible, daily visiting by parents should be allowed, and the importance of admitting mothers with their young children is stressed

The psychiatric needs of sick children should take a prominent place in the training of medical students, nurses, and pædiatricians

Size of Unit

The size of the unit will be determined by the needs of the area and the density of the population, and must have regard to town-planning

In university centres where pædiatrics is taught it is suggested that there should be at least one pædiatric bed or cot for each annual student entry

Small units are undesirable because they are detrimental to satisfactory arrangements for the proper care of children, and to the training of doctors and nurses in this field Units of less than twenty beds are uneconomic, and in closely populated areas children's beds should be concentrated in units of forty beds or more, including beds for both medical and surgical disorders, small units being gradually eliminated

In all units there must be isolation accommodation for infectious cases, enough cubicles for the isolation of babies under one year, for dying and seriously ill children, and for those recovering from operation Accommodation should also be available for the admission of mothers with young children

Where adolescents are admitted there should be separate wards for boys and girls

Site of Unit

There should be a children's hospital or unit of adequate size at each university centre undertaking the training of medical students Much is to be gained from its proximity to the other university departments involved in medical teaching and research, particularly the obstetric department

Inpatient accommodation in general hospitals should be concentrated in central hospitals, but outpatient services should be developed to meet the needs of the population, and a pædiatrician may well conduct a children's outpatient session at a general hospital which has no children's beds The transfer of difficult or obscure cases from smaller units to special children's hospitals should be encouraged It is unnecessary and undesirable to attempt to provide a children's unit in every general hospital or even every area hospital It is essential that the emphasis should be on the best treatment for children and on the best training for those who are responsible for the medical and nursing care of children, and this implies some concentration of children's beds

Medical and Surgical Staff

As stated in the pædiatric committee's interim report of April, 1945, where a pædiatric department is situated at a general hospital it is essential that all children admitted to the hospital should be considered as admitted to the children's department, and should have the benefit of all the facilities available for children, including the services of the pædiatrician

In addition, the need for surgeons interested in and concentrating upon the surgical problems of children, particularly in the newborn period, should be realised, and the larger pædiatric units should provide adequate accommodation for surgical cases

The application and development of special techniques in departments dealing with the investigation and treatment of children is extremely important These specialist facilities clearly could be fully established only in large pædiatric units but these large units should make their resources available to the smaller units in surrounding districts

Particularly there is a need for a personal interest in children and their problems in departments of radiology, anæsthetics physiotherapy, biochemistry, and pathology The staff of such children's departments should be trained and interested in the pædiatric aspects of their specialty

Nursing Staff

The nursing of sick children is one of the most important aspects of their hospital care and requires nursing techniques and experience quite different from those suitable for adult patients Hence the need for nurses with this special education and training in the care of sick children in hospital is obvious

In children's hospitals where training schools for nurses exist and where all nurses have a vocational interest in the sick child, the standard of nursing care for children is likely to be higher than it is in general hospitals where the nurses in training are doing only three months' children's work

The most suitable curriculum and training for sick children's nurses has yet to be evolved Two or three months spent in the children's wards by a nurse training for the general register does not equip her for the care of sick children It is hoped that experiments now running in some centres for combined and integrated training in pædiatric nursing and general nursing may result in a satisfactory solution Nurses undergoing their general training in hospitals without a properly staffed children's unit will need to go for a period to such a unit

The minimum number of trained nursing staff for a unit of twenty beds should be a sister and three staff nurses, all in possession of special training in the care of sick children, to provide such care round the clock

The Staffing of Psychiatric Beds

It is not the intention of this report to set out in detail what specialist departments might usefully be found in large pædiatric units, but the need for psychiatric diagnosis, extended observation, and treatment must be realised

Within the large pædiatric units a child psychiatric unit would be an advantage This could economically be of eight o twelve beds The sister in charge should have had previous psychiatric experience with children In addition to the onsultant and resident medical staff, the part-time services of a clinical psychologist, and a psychiatric social worker will be needed Where treatment is undertaken provision will have o be made for this in staffing the department The whole unit working under the direction of a consultant pædiatric psychiatrist should form a part of the pædiatric service

Education and Recreation

The happiness of children in hospital can be materially nfluenced by the opportunities they have for occupation The use of education in hospital, not only to prevent llness from interfering with educational progress, but also to keep children happy, should be recognised, and a liaison established with local education authorities Provision should also be made for recreation and for play

Branch Outpatient and Casualty Departments

These should be set up both in areas of scattered population and in city areas to meet the needs of the population and to avoid the necessity of small units Such branch outpatient departments should be staffed from the main pædiatric unit, and thus be able to call upon the special facilities of these units

Infectious Diseases

The care of children suffering from infectious diseases should be included in the general pædiatric services for the care of children in hospital The Ministry of Health has stated (R H.B 48 1) "It is of the utmost importance that hospitals or wards for infectious diseases should be closely associated with pædiatric departments, since so many of the patients are children and the problems are similar" Thus the committee fully endorses and considers that when a vacancy occurs on the staff of an existing infectious disease hospital, a pædiatrician should be appointed In every pædiatric unit isolation accommodation is essential, and as large units are developed a block should be included for infectious fevers

Infants in Maternity Units

The committee has already stated that all maternity hospitals and departments should have pædiatricians on the staff and they should undertake full responsibility for the care of the newborn

In the larger units the services of a pædiatric registrar are advisable and the obstetric house surgeons should be directly responsible for the infants to the pædiatric registrar and consultant Every maternity hospital should be linked with a children's hospital or children's department of a general hospital and thus be able to call upon the special facilities of the pædiatric unit

The Family Doctor

Pædiatric units should have the closest relationship with family doctors, who should be encouraged to follow their children while in hospital The proper follow-up of hospital admissions may thus be promoted after they return home from hospital, and the pædiatric unit can perform an educative function

Where pædiatric beds are under the care of family doctors it is important that the pædiatric services should be used and that a pædiatrician should advise on planning as well as policy, taking control, for example, when there is an outbreak of infection

The Local Health Authority

All pædiatric units should have the closest cooperation with these authorities particularly the maternity and child-welfare and school health services and should provide facilities for the postgraduate tuition of clinic doctors and health visitors Through this coöperation the proper follow-up of patients may also be assisted after their discharge from hospital

Regional Hospital Boards

In each region there should be a pædiatric committee to advise the regional board upon questions of planning and policy for the care of children

DISCUSSIONS ON ROYAL COMMISSION

On Tuesday the Special Conference of Local Medical Committees decided to take no decision on the matter of the profession's cooperation with the Royal Commission and to defer the question until the annual conference in June The chairman of the General Medical Services Committee, Dr A B Davies, said that his committee had decided, by 24 votes to 22, at an emergency meeting held immediately before the conference, to put a new recommendation to the conference—namely, "that in view of the latest developments evidence should now be given to the Royal Commission and a decision on withdrawal of services deferred" This decision had been taken after consideration of a letter of April 26 from the Minister of Health to Dr Solomon Wand, chairman of the council of the British Medical Association Confirming what he had said in a talk with Dr Wand, the Minister declared in his letter that there would be full consultation with the profession before implementation of any of the Royal Commission's findings and "that such consultation could of course include any matters relevant to the report or the present dispute" Referring to Dr Wand's fear of some inconsistency between the terms of reference of the Royal Commission and the public statements issued by its chairman, the Minister's letter said that the public statements which had been issued could certainly be regarded as having full validity On the position of public-health medical officers, the Minister repeated his previous assurance that any settlement for others, following the Commission's report, could not fail to be taken into account in considering the position of these doctors, and any claim through the normal machinery would of necessity be considered in the light of the report and of any settlement that followed it Giving the conference his interpretation of this letter, Dr Wand pointed out that the Minister had included the present dispute in the matters for consultation after the Commission's report, and that the broadened terms of reference had been confirmed The issue was now "evidence or fight" If the conference accepted the new recommendation of the G M S Committee, the intervening period would be used to regain unity and strengthen the finances of the Trust, so that action could be taken if later consultations broke down

Many members of the conference were uneasy at taking a hurried decision before they had had a chance to assess how the Minister's letter and the latest statements by the chairman of the Royal Commission had affected the situation Dr Talbot Rogers, on the other hand urged the conference to make an immediate decision His own doubts about the Royal Commission had been resolved and he found it unthinkable that the Commission should go on hearing evidence without having the doctors' case put before it Dr I D Grant warned the conference that to cooperate with the Commission was tacitly to accept unilateral dictation Were doctors to be servants of the Government or equal partners in the National Health Service? Proposing an amendment to defer decision until the annual conference in June Dr Frank Gray remarked that until 9 o'clock that morning the policy of the G M S Committee had been firm Now with almost indecent haste, it had reversed that policy by the smallest possible majority Dr J A Pridham also pleaded for more time to consider the latest developments, and when it came to a vote the conference agreed with him The conference also decided that a decision on withdrawal be deferred, and that the "interim offer of 5% should be accepted without prejudice"

During a discussion on the mechanism of withdrawal from the National Health Service, a proposal that the withdrawal should be total and not phased was defeated, and the conference supported the view that in the event of progressive withdrawal no practitioner should be asked to resign unless 80% of resignations had been collected from the area in which he had been included

The special representative meeting of the B M A held last Wednesday will be reported in our next issue

Central Consultants and Specialists Committee

At its meeting on Tuesday the committee decided to recommend cooperation with the Royal Commission

THE LONDON HOSPITAL RESEARCH BUILDING

FROM its endowment funds the London Hospital has spent £200,000 on a new research building in Ashfield Street, Whitechapel, which will accommodate the research units of the hospital and thus make space in the main hospital for clinical laboratories The new building, which was officially opened last Wednesday, contains

The Hospital Physics Unit

Chief Physicist L A W KEMP, PH D

The London Hospital Physics Laboratory came into being in 1943 but for eight years was concerned almost entirely with radiotherapy physics In 1951 it became responsible to a special physics subcommittee, and was made accessible to all departments Since that time, it has done work for many departments, including the medical unit and the cancer research dental, cardiac, electro encephalographic, ophthalmic, and diagnostic X ray departments, as well as several of the research groups working in the medical college In the field of radiation physics it has come to be known for its specialisation in precision dosimetry

The Hospital Instrument Workshop

Chief Technician E PENFOLD

This workshop has grown out of the initial steps taken to meet the instrument making needs of the physics laboratory In 1951 a full time instrument maker was appointed, but the needs of the laboratory grew rapidly, and it was found that an increasing number of other research departments also required access to first class instrument makers The building of the new research block has therefore been made the occasion for creating the research instrument workshop, administratively separate from the physics laboratory and staffed by five instrument makers (with a storekeeper), provided with 5 lathes, 2 milling machines, 4 power drills, and a surface grinder, together with a guillotine, bending machine, various presses, and welding and spraying equipment The workshop is also equipped, to a more modest degree, for electronic work

Department for Research in Industrial Medicine

Director DONALD HUNTER, F R C P

This department (Medical Research Council) was formed in June, 1943, and its staff includes physicians, chemists, physicists, and technicians Its aim is to study diseases of occupation and their prevention These include (1) acute and chronic poisoning by metals and chemical substances, (2) industrial cancer, and (3) the effects of physical agents such as vibratory tools Field studies are undertaken anywhere in Great Britain and have been made, for example, into fluorosis in an aluminium foundry at Fort William, silicosis among Cornish tin miners, and chronic cadmium poisoning on Merseyside

In the new building there are organic and inorganic chemistry laboratories, a laboratory for radioactive isotopes, a physics laboratory, and a histology laboratory In the animal house a dosing chamber has been built by the staff of the department in which animals can be treated with dust and fume under controlled conditions resembling those of a factory

Venereal Diseases Laboratory

Director I N ORPWOOD PRICE, M R C S

This laboratory (Medical Research Council) is a conjoint laboratory established in 1956 by fusion of the London Hospital Whitechapel Clinic and the M R C Venereal Diseases Reference Laboratories The amalgamation of the two laboratories has made it possible to achieve a much greater output of work without any increase in staff, which consists of the director, two serologists, eleven technicians, and the usual ancillary personnel

Social Medicine Research Unit

Director J N MORRIS, F R C P

This unit of the Medical Research Council was founded in 1948, and transferred to The London in January, 1956 It has a staff of about twelve—medical, statistical, sociological, and clerical In addition, it enjoys much help from the staff of the hospital and from others Depending on the nature of the problem, studies are made on a national or local scale, and though the unit's principal method is that of the field survey, clinical and other methods are used as required

At present it is completing studies on infant mortality, is actively engaged on several inquiries into the causes of coronary thrombosis in middle aged men, and is planning to move into the field of mental disease and the relations of social to hereditary factors Studies are also being made of the working of various parts of the health and social services The advances in the treatment of mental disease mean that many patients are discharged home after a relatively short stay in hospital, and the unit is trying also to assess the needs of such patients in the hope of helping to reduce the considerable relapse and readmission rates In another inquiry the results of teaching and non teaching hospitals in dealing with certain "emergencies" are being compared An intensive study has also been started of the problems of The London Hospital itself

The Dental Research Laboratories

The new dental research department, which consists of four compactly designed laboratories and a small photographic darkroom, will provide much needed space for the expansion of research already being carried out on dental disease by members of the staffs of the dental department and dental school An experimental study of the influence of defective nutrition on the incidence of dental decay is being undertaken by the department of children's dentistry

Cancer Research Department

Director M H SALAMAN, M D

This department was founded in 1930, and transferred to the Medical College in 1948 It is largely maintained by a block grant from the British Empire Cancer Campaign It consists, at present, of six graduate and six technical staff. Members of the department have worked for the most part in two fields (1) chemical carcinogenesis, and (2) the action of tumours on the enzymes of the host Its new, compact, and well equipped laboratories will, it is hoped, enable the department to extend its work

Department of Experimental Surgery

Director Prof VICTOR W DIX, F R C S

This department has been designed in two parts in order to make it possible for work with radioactive isotopes to be done safely The part at present allotted to isotope work consists of a large laboratory, a small animal room, and a dog room, and these rooms are completely isolated from the rest of the department The space allotted to ordinary experimental surgery consists of an operating theatre, two laboratories, a dog room, two small animal rooms, and a larger room which is to be used for X ray work and also as an additional operating theatre It is hoped that it will be possible to do every sort of experimental work in the department except possibly surgical experiments in which long term survival is necessary Later it may be possible to make arrangements to keep animals elsewhere for such experiments

CLINICAL GENETICS RESEARCH UNIT

THE Medical Research Council have established this new research unit, under the directorship of Dr J A Fraser Roberts, at the Institute of Child Health, The Hospital for Sick Children, Great Ormond Street, London, W C 1 The research to be undertaken will include the investigation of congenital malformations and hereditary abnormalities and diseases and studies of the rôle of inheritance in common diseases

In England Now

A Running Commentary by Peripatetic Correspondents

THE forbidding Zeitgeister of *tachisme* and action painting do not haunt the members of the Medical Art Society The keynote of their current exhibition, at Walker's Galleries, 118, New Bond Street, London, is happy innocence The landscape is the most popular form and nearly all the landscapes breathe contentment Dr Terence East's "Douarnenez Bay," Dr Isabel Wilson's "Battersea Reach," Dr Henry Wilson's city ruins, Dr K Shirley Smith's "Wareham," and Mr Ian Robin's "Loch Lomond" are pleasing examples "Near Atcham" is a charming pencil drawing by Dr S Charles Lewsen Among the most attractive of these contemplative scenes are Dr A E O'Donnell's forest glade, "St Martin's Summer," and the sunset-hued oils of Sussex by Sir Philip Manson-Bahr, the society's president, who also contributes a striking picture of a corridor of columns from Karnak

A doctor puts his passion into his work, he is a Sunday painter and perhaps it would be unreasonable to expect passion in his paintings In this exhibition, even where the subject is turbulent, the treatment is often placid, thus the well-drawn windswept moors of Dr Leslie Cole and Mr F N H Maidment do not hammer us to the ground or even gaily whisk off our hats But Sir Harold Gillies's expansive "Flamingoes" has vitality, and Mr T Holmes Sellors, whose water-colours abound in the "wiry lines" beloved by Blake, contributes a small study, "Kitzbuhel," which is one of the most energetic and impressive in the show The deep blue sea in Dr Leonard Simpson's "The Harbour, Monte Carlo" looks as thick and compelling as treacle, and Dr Edith Magill's Connemara landscape is properly sombre, the water is beautifully painted

Mr B N Brooke's romantic imagination is bursting in his two fine pictures His lush "Succulents" is as deeply felt as his portrait "Goan Girl" Dr Josephine Roth has two portraits, of which "The Twisted Smile" is admirable An unusual portrait is Dr Margaret Little's mosaic reproduction Of the still-lifes, Dr Elizabeth Whatley's aquatint is outstanding, and Mr W M Van Essen has a very lively flower piece

He must be a stern critic who has no weaknesses, and mine include primitives (such as the charming oils by Dr Ph Tuttnauer) and Edward Ardizzone, whose strongly individual work is called to mind by Mr G Sparrow's "Pony Sale, New Forest," an accomplished and attractive composition But if I could award a prize for this exhibition, it would go to Dr A Phillips for his splendid bronze head, "Suzanne," in which passion and skill have produced a fine work of art

* * *

Now that the 5% interim tossed into the kitty promises to turn pounds into guineas surely vingt-et-un is the *game for gambling in the N H S ?* Surgery poker, as described by my peripatetic colleague last week, may be all very well for the larger lists with crowded surgeries, but here in the country we have to content ourselves with patient pontoon The profits may be smaller but the returns are much quicker, and in a dispensing practice we have the prescription charges to play with Pontoon is sufficiently flexible to be easily *adapted* to the conveyor-belt routine of hospital casualty and outpatient departments, or local-authority clinics The more sporty-looking patients can even be invited to put their shirts on the luck of the card drawer

As in surgery poker, the preliminaries are much the same for all branches of the service, with the allocation of playing card values to various patient types and the drawing-up of an agreed code of local rules Fate and the buses shuffle the pack before they stack themselves into the waiting-room My partner and I toss for the bank, and then the intercom phone does the rest between our twin consulting-rooms Our receptionist safeguards the spirit of the N H S by seeing that we get a blind deal and she exposes any twists Sticking presents no great problem, but it needs skill not to arouse the suspicions of our more strait-laced patients Poor Miss Prune paled visibly this morning when I greeted her with a disgusted look and absent-mindedly barked "Bust!" Perhaps we have something to learn from the poker-players after all

* * *

The cuckoo has been called the trumpeter of summer Would that I had Jenner's skill as an ornithologist so that I could add something to the natural history of this parasitic bird, which was heard here in the pastoral heart of England on Easter Monday morning I have not yet seen one, though he usually shows himself by his flight and colours as well as announcing his arrival by his voice, still a little hoarse What will his mate do with her eggs this year? The robin, the hedge-sparrow, and the thrush have weeks' start on her Thrushes have already hatched their young The others are well in the middle of the incubation period Even if the foster-mother is deceived, will her own young, several days older, tip the late-hatched intruder out? Perhaps this often happens already, there seems no reasonable explanation why the cuckoo should lay over a dozen eggs except an exceptionally high neonatal mortality

* * *

The American navy, according to the New York correspondent of the *Daily Telegraph* (April 16), is thoughtfully preparing "do it yourself plans" for radio amateurs who wish to tune in on an artificial satellite *during the International Geophysical Year* One of the costly but essential items of this "poor man's version of a million-dollar recordings station" would be a recording device, "but officials believe the amateurs could cut the cost by borrowing a cardiograph from a local doctor"

Local doctors whom we know might offer a choice of stethoscope, auriscope, or hypodermic syringe

* * *

When Cocteau was elected to the French Academy, he said that it is now conformist to be anti-academic He was demonstrating his nonconformity by becoming an academician Perhaps a similar mischievous spirit has prompted Mr Stanley Spencer over the years At this year's Royal Academy exhibition, his alarming *Dinner on the Hotel Lawn* (direct, as they say, from its success at Tooth's) is one sort of splendid painting that is still unexpected in its surroundings Almost equally surprising are his portraits, painted with such sharpness that they seem to lie a foot or so in front of the canvas In the generally romantic atmosphere, earthy realism is *equally surprising It is the keynote of a school of* young painters of whom the best-known are Mr Derrick Greaves and Mr Edward Middleditch Each has contributed *three accomplished* oils, of which Greaves's *Sicilian Subject* and Middleditch's *Irises* are outstanding

In a sense the Academy itself seems to be becoming anti-academic The few abstractions chosen are feeble, and the drawings in the main unexciting, *but* the portraits are often strong and critical, in general they are less than fulsome Fatal charm is dissected, harshness laid bare, rascality hinted at, folly revealed From this exacting test, the medical profession may congratulate itself on coming out so well Mr Harold Knight has painted a presentation portrait of Sir Gordon Holmes, which is *sympathetic and acute*, *and* he portrays both the shrewdness and the humanity of Sir Harold Boldero Mr A R Thomson's sketch of the late Dr Joan Malleson *is charming, Sir Gerald Kelly's Dr John Fulton* is weighty, and Mrs Mary Gillick's medallion of Sir Henry Dale a model of firmness and strength Mr Maurice Codner's *Dr Arthur Bousfield* has quiet dignity Mrs J K Irvine, president of the Pharmaceutical Society, is painted by Mr Norman Hepple, *and* Miss Margaret Smyth, chairman of the General Nursing Council, by Dame Laura Knight There is *a* bust of Dr Douglas Robb by Mr John Kavanagh

The most moving picture in the exhibition is the late John Minton's *Composition, 1957* His reputation among painters was, if anything, even greater than his public reputation The knowledge that it was his last (and unfinished) work adds poignancy to a magnificent painting

Letters to the Editor

MEDICAL STAFFS OF MENTAL HOSPITALS

SIR,—In the light of recent intense interest in the problems concerned with the management and treatment of those suffering from mental illness in its various forms, we should like to draw attention to a matter which has an immediate bearing on the situation—namely, the urgent need for a substantial increase in the medical staffs of mental and mental-deficiency hospitals

This need has already been emphasised in the report of the Central Health Services Council for the year ended Dec 31, 1955, where attention is drawn to both the change in character which is taking place in mental hospitals and the steeply climbing admission-rates After noting that, as psychiatry advances and popular prejudice against resort to mental-hospital treatment lessens, more patients come within the scope of remedial treatment, the report continues

> " These tendencies, encouraging in themselves, are developing in circumstances of great difficulty for the hospitals Most of them were built in the last century and their design is not in accord with modern ideas of the requirements of medical or social treatment They are, for the most part over crowded and short not only of doctors, but of other staff These conditions constitute a challenge alike to hospital committees and their staffs and credit is due to them for succeeding in the face of all difficulties in improving the services available to the community But they need all the help that can be given and more particularly it is essential to strengthen the medical staff "

The wider social and economic aspects of the situation are reflected in a recent public statement to the effect that the loss of man-power in industry due to mental illness of one kind or another is approximately twenty times as great as that which results from industrial disputes

We are satisfied from both our own experience and the information we have received from our colleagues in other parts of the country that the situation is steadily growing more grave Requests for psychiatric advice and treatment steadily increase while the number of psychiatrists to supply this need is woefully inadequate

We would draw particular attention to the fact that the present medical establishments were fixed in 1948 The expansion that is taking place in the volume of work is reflected in the following comparable returns in respect of the mental hospitals and their associated psychiatric outpatient departments in one region for the years 1949 and 1955

	Five mental hospitals (occupied beds 8452)			*Psychiatric outpatient departments*		
	Admissions	*Discharges*	*Deaths*	*No of clinics*	*New patients*	*Total attendances*
1949	3271	2564	587	15	3572	16,159
1955	4741	3864	784	16	4315	21,727

This increase in the turnover of cases in the mental hospitals and the expanding outpatient commitments are two factors which have added to the psychiatrists' work There are others, however, that are important Since the Mental Treatment Act of 1930 there has been a steady increase in the numbers of those seeking admission as voluntary patients with the result that in 1954 and 1955 in one region 70% of the total admissions were in the voluntary category The number certified has diminished proportionately This trend has been mainly responsible for bringing more and more mild and early cases for treatment Such cases demand a much greater amount of the doctors' time since psychiatric management is no longer just a matter of custodial care and attention to intercurrent physical disease, instead, it involves time-consuming psychotherapeutic procedures or the skilled application of the newer physical methods of treatment, together with the social work involved in restoring the patient to useful employment in the community There is a tendency to concentrate the limited medical resources of the hospital on these cases with the consequent danger of neglecting longer-term cases, for whom so much more could be done if time and medical staff were available

With mounting attendances at outpatient clinics the psychiatrist, instead of enacting his proper role of clinician and psychotherapist, runs the risk of becoming a routine prescriber of tranquillising drugs

In the case of mental deficiency hospitals increasing demands on the time of the medical staff stem from the rising numbers of temporary cases, the more frequent review of licence cases, the expansion of extramural activities, and the more thorough investigation of neurological cases, which includes electro-encephalography

With these heavy commitments senior psychiatrists have little or no time in which to perform what should normally be one of their essential functions—that of instructing junior members of the staff and supervising their work

We realise that regional hospital boards are seriously handicapped in dealing effectively with this problem because of the financial restrictions imposed upon them but we are firmly of the view that the situation has become sufficiently serious to merit reference to the highest level

We would therefore urge the Minister to review the matter comprehensively as a pressing national problem, and to introduce without delay effective measures for its control In this connection we submit that a substantial increase in the medical establishments of mental and mental deficiency hospitals, particularly in the senior grades, is a primary requirement

CLEAN BEDS

SIR,—We should like to support the findings of Dr Blowers and his colleagues (March 23) concerning the sterilisation of hospital blankets, and to add some of our own observations For the past six months we have been comparing the properties of woollen and 'Terylene' blankets which have been washed, and then sterilised by autoclaving, after use in a ward in which many full thickness burns are treated

Our method has been to affix to the blankets to be tested squares cut from a similar blanket, which can then be removed for bacteriological tests at each stage of the experiment These test squares were placed in a broth culture and subcultures then plated in the usual manner The blankets were washed at 110°F with a detergent, 'Syndet 4,' using a technique of acid washing conditions with low foam production for maximum detergency They were then dried and autoclaved in a large dressing drum at 20 lb per sq in for 25 min

The proportion of area lost (i e, shrinkage) after only six complete processes (washing and autoclaving) was 47% for the woollen and 4% for the terylene blanket In addition the woollen blanket " felted " into a hard coarse material, the colour changing from cream to light grey, whilst the terylene blanket remained soft, white, and fluffy The bacteriological tests showed that the blankets, when new, were infected with a variety of organisms including *Neisseria mucosus*, *Streptococcus viridans*, and coagulase negative *Staphylococcus aureus* After being used on the patients the test squares then grew, in addition, coagulase positive *Staph aureus*, *Pseudomonas pyocyanea*, *Escherichia coli*, and *Bacillus subtilis* These types of organisms were still found after the washing process, and often further varieties of organisms were isolated, showing that the washing process did nothing to remove the bacteria but merely distributed them throughout the blankets After sterilisation (autoclaving), however, the blankets showed either no growth or the growth of a few types of non pathogenic organisms

The good qualities of terylene blankets are therefore:

(1) There is little change in weight or size after repeated washing and autoclaving.

(2) There is very little change in the texture of the material after washing and autoclaving.

(3) They are non-inflammable.

(4) They are preferred by the patients because of their warmth and softness.

There is one disadvantage, the accumulation of a high static electrical charge. This would prohibit the use of terylene blankets in the operating-theatre, and it is, therefore, suggested that Turkish-towelling blankets, dyed in a distinctive colour to act as a reminder, could be used to accompany the patient to and from the operating-theatre.

Although blankets will quickly become reinfected when used on a patient with full-thickness burns, sterilisation of blankets will ensure that no organisms are added to the patient's wounds at the start of his treatment.

Liverpool W. ATKINSON.

GOVERNMENT AND PROFESSION

SIR,—In your last issue "Blackleg," who does not give his name, complains that members of the B.M.A. council and of the General Medical Services Committee, who were not members of his division, attended its meeting. But what is the job of elected members of the G.M.S.C. and council if not to attend meetings of divisions within their constituencies?

He speaks of a "party line." There is no party line: every decision made has been made by strict majority voting. If "Blackleg" does not attend meetings, it is his own fault if these majorities decide things he does not like. To do everything by postal ballot for 70,000 B.M.A. members plus 10,000 odd non-members would increase the subscription to the B.M.A. by at least a guinea. So even that idea is not a good one.

He says that to many people the policies of phased withdrawal and boycott of the Royal Commission seem unethical. Then perhaps it is unethical for such people to take the money won for them by those who negotiated the Danckwerts increase in 1952 or the hospital increase in 1954? Does your correspondent suppose that a beneficent Ministry of Health looks after his interests and is only too glad to ask the Treasury for what it thinks he needs?

If he regards withdrawal as wrong because it will "hurt the patient," I can assure him that the patient will not get hurt: the Government, for political reasons, will see to that. The only risk is that this Government, being Tory, may be trying to wreck the National Health Service and pin the responsibility on us. (After all, we are on record on two occasions as opposing the imposition of charges on patients.) No, even if we withdraw, the Government when the time comes will make interim arrangements by which the public will have a free service, even if this is done through the National Assistance Board refunding the money that patients have paid out to doctors and for chemists. In any case, as the Government so often remind us, this is not our problem: it is their duty, by law, to provide a Health Service, not ours. We are merely asked to contract to do Government work at *agreed* rates and on *agreed* terms. If one side to this agreement rats, what is the other side to do? It can (*a*) go to court, or (*b*) withdraw from the agreement and negotiate a fresh one. If we had ratted the Government would have been the first to do either (*a*) or (*b*). "Ethics" —apart from the ethics and honour of pledged agreements —do not enter into it.

London, W.C.1 J. L. MCCALLUM.

SURGEON'S "PRIVILEGE"

SIR,—Up and down the country one hears from time to time of attempts by hospital administrators to break a tradition which they are told by the financial representatives of the Government is illegal. I refer to the provision of refreshment to the surgeon and his colleagues during operation sessions when they are prevented from going to their homes or other normal places of refreshment. Sensible administrators, particularly those of the older school, turn a blind eye to any question of restriction. Lest younger men should become overwhelmed by authority, the whole matter should be clarified nationally.

Surgeons and their immediate colleagues do not ask for "privilege": the matter is much more fundamental. Operative surgery is an exacting enterprise concentrated without regard for time upon one purpose. The patient who is the centre of this purpose should, with the surgical team, be identified as a unit and for no matter how many hours the work continues by day or by night every aspect of the comfort and well-being of the complete unit must be safeguarded. The custom of sustaining the surgeon and his colleagues under these conditions is a humane tradition of British hospitals; the ultimate object is the safety of the patient. The exercise is like that of a naval vessel in action: it cannot be measured in the time taken or in the personal service received by the crew.

Exeter NORMAN CAPENER.

INSULIN TREATMENT OF SCHIZOPHRENIA

SIR,—We read with great interest the article by Dr. Ackner and his colleagues (March 23).

We think they and your readers would like to know that we pointed out the non-specificity of insulin treatment as early as 1939.[1] Our findings were based on 419 patients, of whom 118 were given insulin shock and 61 leptazol ('Cardiazol'): 218 had no active treatment (control group).

The follow-up included 283 very carefully investigated cases. Two of our final conclusions were: (*a*) insulin treatment had no effect on new *acute* cases of schizophrenia; and (*b*) in *chronic* cases improvement was no greater than in the control group—i.e., 10%.

We think our experience serves to confirm the conclusions of Dr. Ackner and his colleagues.

St. Istvan Hospital, Budapest.
T. LEHOCZKY
MARGARET LEHOCZKY.

SIR,—Before the two camps in the issue of insulin treatment become too firmly entrenched, it will be appropriate to point out a line of argument which so far has not been adduced. Dr. Ackner's findings, obtained by an incomparably exact technique, are unassailable, though one would have wished for a larger material and for a longer follow-up. A fine demonstration of an object-lesson, the findings must be made the starting-point for unrelenting re-thinking.

While nobody has ever been biologically so naïve as to see in insulin a specific therapeutic agent in schizophrenia, and while everybody has kept in mind that what matters are the neurochemical reactions to hypoglycæmia, very few have proceeded from there to a wider biological field. If one biological lever to the adaptatory mechanisms of the organism can produce good results, then, it can be concluded, other biological levers can produce just the same. The rhythmic training of the homœostatic mechanism which insulin treatment incorporates—in other words, this slow process of restoring elasticity to a system which has been in danger of becoming stiff—can in principle be replaced by any similar technique.

White mice weighing about 20 g were given hexo arbitone sodium 150 mg per kg or methylpentynol 400 mg er kg intraperitoneally Fifteen minutes after the induction narcosis, bemegride 50 mg per kg was given intravenously he results are shown in the accompanying table

In a few other preliminary experiments with chloral hydrate, similar tendency to shortening of the sleeping-time was oted In several animals narcotised with hexobarbitone, onvulsions were noted after bemegride had been given o such effects were observed in the methylpentynol group

Our results demonstrate that bemegride is effective gainst a non-barbiturate narcotic, methylpentynol, hich has previously been denied [6] These findings seem confirm the opinion that bemegride acts mainly as a entral analeptic The experiments are being continued

AN ALTERNATIVE TREATMENT OF OSTEO-ARTHRITIS OF THE HIP

Sir,—My experience of the effects of radiotherapy in steo arthritis of the hip is similar to Mr Murley's April 20), and about a year ago I had to find an alternaive for a woman of 70, who had severe joint damage and was in such pain that she could not sleep at nights

She was almost bedridden, her general condition was eteriorating, and owing to myocardial degeneration she was nfit for operation My colleague, Mr Godfrey Hutchinson, onsultant dental surgeon to the Newcastle group of hosntals, agreed to treat her by hypnotic suggestion The result was very satisfactory She was given physiotherapy during er course of suggestion therapy, but it had to be stopped for ear of acute heart failure

She now sleeps well and her general health has improved he walks indoors at home, but always holding on to the urniture Her range of hip movement is now voluntary whereas previously it was difficult to obtain any movement, even passively, owing to spasm

She is not entirely free from pain and she is still very limited n what she can do, but this is a safeguard for her weak heart

I recommend this method as an alternative to heavy sedation and a prolonged painful bedridden existence I am most grateful to Mr Hutchinson for his cooperation in my dilemma

EPIDEMIC VERTIGO

Sir,—I have recently seen 5 cases of acute vertigo 2 patients had no associated signs and returned completely to normal within a week, they were not investigated The other 3 had coarse, rotatory nystagmus but no other physical abnormalities

Blood counts, erythrocyte sedimentation rates, radiographs of chest and skull, and examinations of the cerebrospinal fluid were normal Caloric tests were normal in 2, the other patient gave no response on stimulation of the right labyrinth Audiograms in this and 1 other patient were normal All 3 patients were afebrile The longest period for recovery was a month The patient with an abnormal caloric response still had this when last seen, six weeks after the onset His nystagmus had disappeared and he was quite steady with eyes open or closed

The patients were seen over a period of eleven weeks and had had no direct or indirect contact with each other Consequently nothing could be inferred about the epidemiology of the condition It seems likely, however, that sporadic cases do (perhaps regularly) arise The ætiology of the condition was unknown, precipitating infection, emphasised by Dix and Hallpike [7] and Moller,[8] was not evident The lesion was thought to be situated centrally to the labyrinth and the term "central vestibular vertigo" was used Such a term would include affections showing a similar natural history and previously called virus labyrinthitis, vestibular neuronitis, brainstem encephalitis, and epidemic vertigo It should exclude cases with progressive tinnitus or deafness and those where the ætiology is known

T B. Stretton

ÆTIOLOGY OF PRE-ECLAMPSIA

Sir,—The letters of Dr Morris (April 13) and Dr Schuurmans (April 20) suggest that some confusion may exist about structural stress and strain relationships and hydrostatic pressures in the uterus It is important to recognise which factors can and have been measured, and to avoid lax terminology, which leads to the misinterpretation of available evidence

Intra-uterine, or intra-amniotic, pressure arises from the work of the uterine muscle and the intra-abdominal pressure The uterine muscle component is the greater, and, for simplicity, is considered alone in this letter The uterine contents are held together against the forces of gravity by the forces in the walls of the uterus During a contraction the fluid-like contents of the uterus are gathered into a pear-like shape, which tends to become more spherical (largest volume for least surface area) as the contraction increases in intensity The volume of the contents remains nearly constant With the change in shape the hydrostatic pressure is raised For a given shape the rise in intra-uterine pressure is a measure of the average increase of the tensile force over the whole uterine wall

The tensile force is the force required to approximate the edges of an imaginary cut perpendicular to the direction in which the force is being considered Clearly the force depends on the size of the cut and it is therefore better to use the term *stress*, which is the tensile force per sq cm of cross sectional area Where tensile force in the wall is greatest the wall thickness tends to be greatest, thus making for a substantially uniform stress distribution, at least over the corpus

Tensile force at any point is directly proportional to the intra-uterine pressure and to the radius of curvature of the wall in the same direction

The intra-uterine pressure is not uniform throughout the uterus, because of the greater weight of water upon the lower parts It is customary, therefore, to express the pressure related to the highest point of the uterus in the supine patient The pressure difference between fundus and cervix may be as much as 25 cm water in the standing patient

The relation of pressure to tensile force has been very thoroughly discussed by Halliday [1]

The change in length per unit length of a stretching or contracting material is called *strain*—positive strain for an increase in length and negative strain for a decrease in length During a contraction, the myofibrils and their surrounding fibrous tissue show negative strain The interconnecting fibrous tissue between the muscle cells shows positive strain The response of strain-sensitive nerve endings would depend upon the part of the structure to which they were attached

In patients with gross uterine distension the walls are thinned and curvatures decreased, with the result that for the same tensile stress in the walls, and the same strain, if the nature of the muscle is unaltered, intra-uterine pressures are reduced

Measurements upon patients show that

In hydramnios intra uterine pressures both between and during contractions are below normal Hydramnios may be either the cause or the result of the low pressure, but when liquor is removed the pressure rises

In pre eclampsia (and one case of eclampsia in Athens), the intra uterine pressures and wall curvatures, and hence wall tensile forces, are within normal limits

[8] Möller F *Acta psychiat, Kbh* 1956, 31 107

[1] Halliday, E C *J Obstet Gynæc, Brit Emp* 1954, 61, 811

To quote an apparently far fetched example in 1954 Lovett Doust[1] claimed good results in schizophrenia by "rhythmic sensory bombardment" (photic or sonic), which he tried to connect with the principle of desoxygenation. 25 years ago when Mayer Gross[2] reported on the therapy of schizophrenia, he quoted (with due caution) a review[3] of 1600 cases (in the literature) subjected to pyrexial treatment, which was widely advocated in the first quarter of this century. No doubt the third quarter will see an attempt to treat the disease with hypothermia, which now is so much in the *foreground*.[4]

In the present situation, the studies on the relationships between schizopathy and endocrinopathy, inaugurated by Bleuler[5] of Zurich and supported by our Bristol and St Ebba's groups (April 13), must be allowed to ripen. This is nothing more than a revival of the much earlier metabolic idea underlying Gjessing's studies in catatonics.[6] If this trend bears fruit, as it may, we shall not expect the psychotherapists of schizophrenia to retreat into the next trench and to abandon schizophrenics as untouchables. Similarly, there is no need for clinical workers who value the insulin technique for its standardisation, and for the prognostic criteria worked out on an immense material, to abandon it. Some will find all the trouble worth while in selected cases without neglecting *other therapeutic approaches to personality as a whole*.

The biology of the human organism and the theory of its adaptation are very complex matters, and any attempt to claim monopoly for one isolated mechanism, or one isolated level of behaviour, will lead to fallacious conclusions. While neither side is yet victorious, both will continue to share in an honest endeavour to master the problem.

Reading STEPHEN KRAUSS

THIRTY-MINUTE SCREENING TEST FOR PHÆOCHROMOCYTOMA

SIR,—Dr Hingerty's test (April 13) has the merit of requiring no special apparatus, but his reporting of results in terms of µg of pressor amines excreted seems to me open to criticism, for the following reasons.

(1) No results are given for percentage recovery of noradrenaline added to urine. Using the technique described by Dr Hingerty, but taking noradrenaline as comparison standard without prior adsorption and elution, recoveries, in my experience, have been around 30%, and have varied considerably in different estimations. Admittedly the extent of error from this source could be partially reduced if a recovery estimation was included in each analysis. Dr Hingerty's comparison standard, however, is prepared in advance and kept for repeated use on the assumption that the percentage *recovery remains constant*.

(2) Visual comparison of fluorescence intensity is likely to be misleading, particularly at low concentrations, where even a threefold difference of intensity is by no means obvious unless instrumental comparison is made. The presence of other fluorescent substances, not infrequently encountered in urine extracts, could make even semiquantitative assessment impossible unless filters were used, as in commercial fluorimeters.

(3) The details given of the method of preparation of alumina are insufficient to allow of exact repetition; it is, however, known that the temperature of drying and the final water content of the "dry" alumina exert a considerable influence on its adsorptive properties. Dr Hingerty may have been fortunate in having alumina which regularly gave quantitative recovery of pressor amines, but my experience in this respect has been discouraging.

A simple routine method for estimation of pressor amines in urine is certainly required, but I am not convinced that the method described is sufficiently reproducible to be useful, except possibly when excretion is enormously increased. To judge by published data, the output of catechol amines in phæochromocytoma is not *always increased to this extent*.

Lastly, the test might perhaps be more accurately described as a sixty-minute one. If a set of controls and standards is prepared at the same time, two hours is a more likely requirement.

Department of Clinical Chemistry,
Royal Infirmary Edinburgh SAMUEL C FRAZER

BRONCHIAL LAVAGE

SIR,—I wish to thank Dr Trobridge for describing his simple technique of bronchial lavage (March 16). With a little practice, the method may be further simplified by posturing the patient while the saline is poured in (as is done during bronchography). This will avoid the theoretical dangers of "flooding and soiling" other parts of the lung. Recently, I had the opportunity of finding acid-fast bacilli in the bronchial lavage of a woman who had persistently negative sputa and laryngeal swab. She had eosinophilia in the blood and had in fact been transferred to a general medical ward.

In view of Dr Trobridge's report, every patient who has difficulty in raising sputum should have bronchial lavage instead of the traditional swabbing of the larynx or washing of the stomach.

IS BEMEGRIDE A SPECIFIC BARBITURATE ANTAGONIST?

SIR,—In 1954 Shaw et al[1] described their investigations of bemegride ('Megimide,' ββ methylethylglutarimide) and claimed it to be a barbiturate antagonist. They based their opinion on experiments in which they had found a reduction of sleeping-time in animals of several species that had been narcotised with pentobarbitone, barbitone, or phenobarbitone, as well as on clinical experience. In 1955 Shaw[2] stated that the action of bemegride was specific and that it did not affect the depressant actions of other anæsthetic agents such as ether, chloroform, and morphine.

Lately, voices have been raised against the specificity of bemegride, which is instead believed to act mainly as a central analeptic. Thus Hahn et al[3] have stated that it is "a functional and not a competitive antagonist." Danish work suggests that bemegride does not shorten barbiturate coma in man, that the patients do not wake up at higher serum-barbiturate levels, and that the rate of elimination of barbiturate from the blood is unaltered.[4] Others also emphasise the potent action on reflex activity and respiration. "It is difficult to explain these clinical results and observations as the action of a simple biochemical antagonist."[5]

We believe that bemegride is a valuable drug in the treatment of certain forms of barbiturate intoxication, but we do not think that the mode of action has been sufficiently clarified. We therefore compared the action of bemegride against barbiturates with its action against other narcotic agents.

ACTION OF BEMEGRIDE ON NARCOTISED MICE

Drug	No of animals	Duration of narcosis (min) with standard error of the mean (min)	Difference
Hexobarbitone	29	118 ± 5	38 ± [illegible] P < 0·001
Hexobarbitone, then bemegride	18	80 ± 4	
Methylpentynol	35	29½ ± 2	
Methylpentynol, then bemegride	45	37 awoke at once 8 after 7–180 min

[6] Rosen J *Nord Med* 1957 57, 23
[7] Dix, M R, Hallpike C S *Proc R Soc Med* 1952, 45, 311
[8] Möller I *Acta psychiat, Kbh* 1956 31, 107

[1] Halliday, E C. *J Obstet Gynæc, Brit Emp* 1954, 61, 811

After concealed accidental hæmorrhage both pressure and wall stress is considerably increased for a long time

The changes in strain in the uterine walls occurring from time to time in a normal patient, with changes in posture or with Braxton Hicks contractions, far exceed the differences between one patient and another, and the uterorenal reflex pathway, if it exists in woman, would often be stimulated in all patients

Two facts, however, need to be ascertained before the uterorenal reflex theory of toxæmia is discarded Firstly, do pre-pre eclamptic patients have a phase of raised intra-uterine pressure before they become pre eclamptic? Secondly, do patients before or after they become pre eclamptic have more frequent Braxton Hicks contractions and hence stimulate this hypothetical reflex more often? One might inquire whether they have premature development of the lower segment and cervix, where positive strain sensitive nerve endings would be expected to exist Toxæmic patients certainly have shorter labours for the same weight of baby, as judged by the duration of painful contractions, than normal patients

London, W C 1

C N SMYTH

THE STAPHYLOCOCCUS PLAGUE

SIR,—Your leader of April 6 suggests methods of reducing the dissemination of staphylococci but does not refer to the possible use in hospitals of germicidal ultraviolet light for the inactivation of air-borne micro-organisms

The germicidal ultraviolet tube (T U V Philips Electrical) is widely used in laboratories and in industrial processes to produce "germ free" air conditions These discharge tubes are made from a special glass, transmitting ultraviolet of wave-length longer than 2000 Angstrom units, a high proportion of the radiant energy produced is at 2537 Å

Ultraviolet of 2600 Å wave length prevents the reproduction of micro organisms The ultraviolet from a T U V will inactivate *Staphylococcus aureus* in culture with a dose of about 5 micro watt seconds per sq cm

Ultraviolet tubes of 15 and 30 watts resemble fluorescent lamps in appearance and the same type of control gear is required for operation The tubes can be mounted in air ducts or in aluminium reflector units, or used bare in suitable situations Bacteria in the air within the effective radiation of the tube are inactivated, and inactivity of the order of 99 9% can be obtained

There are many possible applications of this germicidal ultraviolet radiation in hospitals—for example, to produce an almost sterile atmosphere in operating theatres, anæsthetic rooms, clean surgical dressing rooms, and wards, and to inactivate the immense numbers of floating bacteria in septic wards, septic surgical dressing rooms, soiled linen rooms, and corridors leading from similar potent sources It should be possible to devise a portable tube carrier for use over a bed when heavily infected dressings are being changed

Patients and staff can be protected from direct radiation by simple means, ordinary glass spectacles or plastic visors protect the conjunctiva, which is especially susceptible to short wave ultraviolet radiation The American Medical Association has approved the use of germicidal tubes in hospitals and has produced tables showing safety limits of intensity of radiation to which patients and staff can be exposed

The movements of patients, staff, and bedding from septic wards to "clean" areas causes heavy air contamination, but if T U V can be used to inactivate these floating millions of bacteria the possibility of cross infection becomes remote and a hospital should then become a "clean and wholesome sick-house"

I believe that the initial cost of installation is greater than that for fluorescent tube lighting, but the running costs should be no higher, the life of T U V is relatively long—averaging 2500 hours

[illegible] Northumberland

JOHN W JAMES

SHERRINGTON CENTENARY

SIR,—A memorial lecture as suggested by your corr pondents (April 20, p 841), seems to me to be inadequate recognition of Sherrington's work as a ve great scientist and a truly great man As, however, t die is cast, may I suggest that "lecture" be replaced "lectures," and that they be founded on the same li as the Silliman lectures, among which Sherringto greatest work *The Integrative Action of the Nervous Sys* is enshrined?

London, W 1

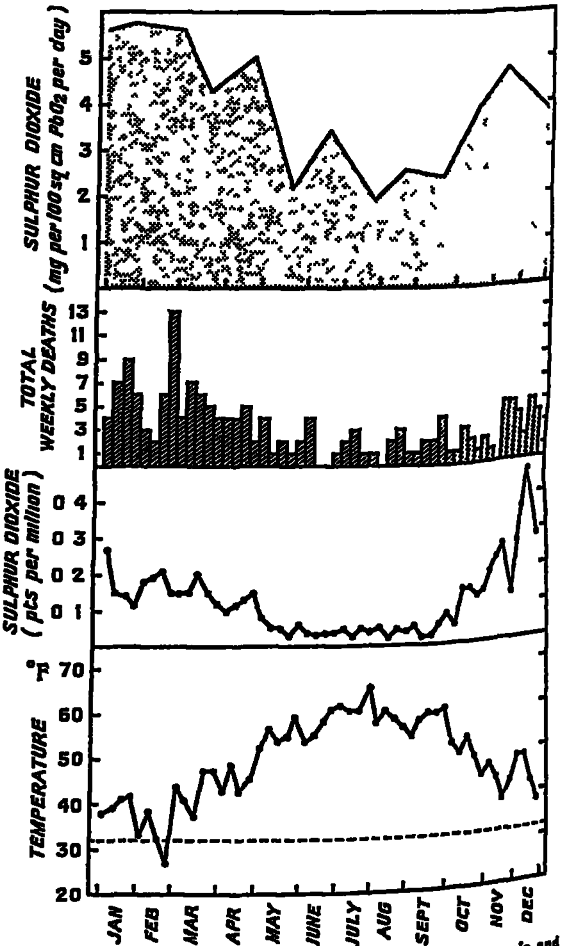
J HERBERT PARSON

ATMOSPHERIC POLLUTION, TEMPERATURE INVERSION, AND DEATHS FROM BRONCHITI

SIR,—Bronchitis is rarely given as the first cause death in this country The deaths shown in the accom panying figure are those recorded as due to respirato diseases (other than lobar pneumonia and cancer) a circulatory failure, where no definite ætiology is give The figures were extracted from the lists reaching th department during 1956

At the top of the figure is given the rate of absorptio of sulphur dioxide on to a lead-peroxide candle T values are the averages of monthly readings taken three sites within the district Below are given, week b week, the mean daily temperature (measured at Kew and the mean sulphur dioxide content of the atmosphe as measured at one point in the district I have n information about the occurrence of temperatu inversion

The general trend of the figures is the same as th recorded by Dr Roberts and Mr Batey (March 16



Deaths due to respiratory disease (other than lobar pneumonia and cancer), sulphur-dioxide readings, and mean daily temperature at Kew out it will be seen that the week ending Feb 25 is exceptional, having 13 recorded deaths Of these, 4 were ascribed to heart-failure, and of the other 9, bronchitis was mentioned in 6 cases This was the week of the great freeze, but the sulphur-dioxide content of the air was not unduly high In the week ended Dec 22 fog was experienced in London and the sulphur-dioxide content rose, but the number of deaths recorded was not unusual

These figures seem to indicate that extreme cold may be inimical to the survival of bronchitic patients

Public Health Department
City of Westminster
G W PIPER

INCREASED PITUITARY GONADOTROPHIN ACTIVITY AFTER DEGENERATION OF SEMINIFEROUS TUBULES PRODUCED BY NITROFURAZONE

SIR,—In his interesting article (Feb 9) Dr Nissim has described the lesions in the testis in mice fed for a period of 2–5 weeks on a diet containing 0 04–0 6% nitrofurazone If a mouse eats 5 g daily of a diet containing 0 6% nitrofurazone, the quantity of nitrofurazone ingested is considerable—the equivalent of 90 g nitrofurazone a day for a man weighing 60 kg

When the diet contained 0 04% nitrofurazone Dr Nissim did not notice any damage of the testis This latter dose is equivalent to 6 g a day for a man weighing 60 kg Such a dose is not in common use

Nitrofurans have been used with effect in the treatment of various infections, and we think that Dr Nissim should have mentioned that the doses given to mice in his experiment represent large doses never used in man

Bucharest Rumania
V BOTGROS

AMIPHENAZOLE

SIR,—We note that Dr Dundee (Feb 16) has confirmed our earlier finding that amiphenazole, in combination with large doses of morphine, is of benefit in the treatment of intractable pain of terminal carcinoma Dr Dundee states that amiphenazole does not always counteract the nausea and vomiting due to morphine We would agree with this In results about to be published, we show that the incidence of vomiting in healthy volunteers due to a dose of 20 mg of morphine is about 30% When morphine is given to carcinoma patients in pain the incidence of vomiting is almost negligible The above-mentioned vomiting in volunteers is not controlled by amiphenazole but it is almost completely, by oral cyclizine and entirely by intravenous cyclizine The low incidence of vomiting when morphine is given in the presence of pain misled us with respect to the antiemetic action of amiphenazole

Dr Dundee finds that the respiratory depression induced by morphine is not always relieved by amiphenazole We would also concur with this finding We have now had some experience in the use of amiphenazole as a respiratory stimulant, both specifically against morphine and non specifically, over the past two years

The variable results obtained by ourselves and others may be due to the use of too small a dose Both from pharmacological evidence and clinical experience one can say that amiphenazole is a very safe drug On two occasions recently we have successfully used amiphenazole in single intravenous dosages of 150 mg to treat non-specific respiratory depression As we have already pointed out[1] doses of up to 300 mg may be given intravenously, at a single injection These large doses may be repeated at hourly intervals for several hours if necessary

THE STUDENT AND SEX EDUCATION

SIR,—Dr Sandler (April 20) is to be congratulated for pointing out the inadequacy of our teaching in the general field of sex education

He goes right to the root of the matter when he says that to be an adviser one must have not only the necessary knowledge and experience but also a basic spiritual depth Last year the Birmingham medical students (perhaps unwittingly) underlined this when they arranged a forum on the subject of marriage guidance, they invited a gynæcologist, an experienced general practitioner, who had for years assisted at the Family Planning Association, and a minister of religion, the Rev H L Tizard

Has the time now arrived, as Dr Sandler suggests, for a set course of lectures on the functional aspects of marriage, the problem of birth control, &c , as outlined in his essay ? My own view is that instruction is best integrated into " medicine "—particularly, of course, into gynæcology and obstetrics

In Birmingham we are fortunate in our clinical material which allows us to " dilute " our student-instruction to 2 or 3 students per firm This allows us to avoid " classes " in outpatients, and although a student in his early days does not probe deeply into the functional side of marriage in his patient's history, nevertheless, there is on our unit case-sheet the heading " dyspareunia " With individual teaching of students the more detailed histories taken in private by the consultant can be gone over with the students when the patient has gone I give these as examples of integrating teaching of the abnormal into gynæcology, but an interest in the normal is also stimulated and our library has a suitable stock of books by authors such as Wright, Macalister, and Tizard Moreover, the Marriage Guidance Council and the Family Planning Association both accept our students as visitors, and of course Roman Catholic students are recommended to visit centres for members of their Church or to discuss problems peculiar to their Church qua sex education and birth control with colleagues in gynæcology who are also Roman Catholics

Lastly, I thought Dr Sandler should have made more of the educational value of a resident three months in an obstetric unit Nevertheless, his main arguments are, I think, proven and those of us who are taking part in the teaching of students must obviously accept greater responsibility But I make a plea for further and improved teaching which will be integrated into the subjects of gynæcology and obstetrics The idea that a further subject (" sex-education ") should be established with its own lecturer and perhaps its own examinations makes no appeal to me

Department of Gynæcology and
Obstetrics University of Birmingham
H C MCLAREN

SIR,—Dr Sandler's excellent article comes at a time when it is particularly welcome The General Medical Council, the Royal College of Physicians, the College of General Practitioners, and the British Medical Students' Association are all earnestly considering the problem of medical education Later this year the General Medical Council will make its recommendations, which, it is sincerely hoped, will give the medical schools a free hand in the rejuvenation of their teaching

Proper instruction in normal marital and sexual relations is sadly lacking from the present curriculum Even though the modern concept is the production of a basic doctor who can then specialise in general practice, cardiology, or whatever he desires, surely normal marital relations in all aspects should be taught wisely and sensibly during the clinical years This is of a far greater importance than watching œsophagectomies and ventriculograms

As that all too rare occurrence amongst British medical students, a married man with a family, I am acutely aware of the inadequacy of the training of my fellow students There can of course be no substitute for marriage itself as a teacher, and it is very much open to debate whether the early marriage of medical students should be approved or frowned upon

At a time when so much of a doctor's life is spent in dealing with functional illness and so much of functional illness stems from sexual and marital difficulties, may I make a plea to our teachers to read with care Dr Sandler's article and implement his suggestions, so that we may produce doctors and not scientists

E J R ROSSITER

FLUORIDATION OF WATER-SUPPLIES

SIR,—Now that some experience has been gained in the fluoridation of water-supplies and that the benefits of fluoride-rich water are so well known, we feel that the time has come for the next step in this campaign for better dental health

It seems to be widely believed that fluoridation is different in principle from other methods of water treatment, particularly as regards the rights of the consumer and the powers and duties of water undertakers

We, however, maintain that the duty to supply wholesome water should now be understood to mean a duty to ensure an optimum fluoride content We propose to make what appears to be the first complaint ever made under the Metropolis Water Act of 1852, which provides for an inquiry by the responsible Minister into a complaint by 20 or more householders as to the quality of the water supplied by the Metropolitan Water Board

Our complaint is that the water contains much less fluorine than does the more wholesome water supplied by certain other water undertakers We invite any of your readers who are interested, and especially those who are parents and householders dependent on the Board for drinking water, to communicate with us at 73, Harcourt Terrace, London, S W 10

ANÆSTHESIA FOR FRACTURES OF THE FEMORAL NECK

SIR,—I have read with interest the paper on this subject by Dr Murray and Mr Stuart Young (March 23)

In my experience it is unnecessary to raise the blood-pressure preoperatively or during operation in those patients who have received chlorpromazine as part of their premedication Provided a depleted preoperative blood-volume is remedied and a constant blood-volume is maintained during the operation, the reduction in blood loss and the protection from stress afforded by this drug benefit the patient

Should it be deemed essential, however, to raise the blood-pressure in a patient who has received chlorpromazine, I would have thought an overall vasoconstrictor such as noradrenaline would be preferable, for chlorpromazine, like dibenamine, partially blocks the pressor effect of certain amines such as methedrine, and the pressor effect of intravenous adrenaline may be actually reversed, resulting in a further fall in blood pressure

The dose of lignocaine (' Xylocaine ') recommended for local infiltration (i e, 100 ml of the 1% solution) I would regard as dangerous, particularly in the elderly patient In my view 500 mg of lignocaine should not be exceeded, this restricts the volume of the 1% solution to 50 ml A further safety factor is to use adrenaline with the lignocaine As the latter has no vasodilatory properties the adrenaline is effective in a concentration as dilute as one part in a million, and this local vasoconstrictor effect is not antagonised by the adrenoly properties of chlorpromazine

Furthermore, as adequate analgesia can be obtai with $^1/_2$% or even $^1/_4$% lignocaine, and as the toxicity the drug varies in geometrical ratio to its concentrati it follows that much larger volumes of these dil solutions could be safely used

Hull W N ROLLASON

THE Rh BLOOD-GROUPS

SIR,—Dr Wiener usually deals with points ma against him by changing the subject By contrast propose to deal with the paragraphs of his letter (April one by one, with the exception of his criticism of Renton and Dr Hancock which is, I think, best answer by those authors themselves

There are perfectly good distinct symbols for bo phenotypes and genotypes in the CDE system, and t worker can use whichever suits his purpose best Mo of Medicine involves choosing between possibilities varying degrees of likeliness and it is difficult to see w the serologist alone is debarred from doing this

Since there is no international agreement, no terminolog CDE or Rh Hr, can be considered as "official" Unl Wiener, Fisher and Race have never made false claims to "International Nomenclature" Nevertheless all the sy onyms given can be readily understood, and none wou provoke the user of one of the others to an outburst in pri Most workers would probably prefer to use *CcDee for t* phenotype and CDe/cde for the most likely genotype cannot see that the existence of these synonyms is a "contr diction" But what about Dr Wiener's use of anti Rh_1 a anti Rh_2? In 1943[1] they meant anti D and anti C respe tively, now they mean anti C+D and anti D+E

The designation -D- describes the serology of this blo well, far better than Rh_0^x Whether the dashes denote gen which determine nothing or an absence of genes is rath academic The reasons for thinking this is a deletion a quoted by Race and Sanger[2] but this blood type could, course, be called c°De° without damage to the CD nomenclature as a whole

The "shorthand" symbols are colloquialisms, and lik many colloquialisms are survivals of earlier usage They a not an essential part of the system, and one of their chief us is probably as an aid to transatlantic understanding R_1R_2 *not directly related to CDe/cDE any more than Et is relate* to C_2H_5, but if one remembers the simple equivalence a *serum reactions and all other possible genotypes giving the* can be directly deduced CDE workers have no need fo tables six pages *in length of possible and impossible childre* of various matings such as Wiener[3] gives

The complete sentence on p *181* of Race and Sanger book[2] is "Now that anti f is commonly found in anti c ser we feel doubtful about the identity of these two examples o anti d, their published reactions however exclude anti f"

The derivation of the order DCE from a theory *of extremely* rare crossing over was a suggestion of Fisher and Race,[4] and has never been put forward as incontrovertible *fact* Their actual words were "It is tempting to think that these fou rarer genes in the British population are maintained by suc occasional cross overs" This, surely, does not look like sweeping claim of world wide application Whatever the tru order may be the conventional order is likely to remain a CDE, just as an electric current still conventionally flow against the electron stream

As Race and Sanger say in a footnote on p *113 of the* book, the difference between Fisher s and Wiener's theories "the highly academic and interesting point whether the thre allelomorphic sites of Fisher are to be placed within or withou the boundary of one gene" Dr Wiener tries to give th impression that Fisher and Race have based their whole theor and nomenclature on C, D, E, c, d, and e being independen genes, and have since retreated from this position This is, a Dr Wiener well knows, not true Race's[5] original paper says "These single letters refer to antigens and their correspondin

---

1 Wiener A S Blood Groups and Transfusions Springfield, Ill 1943
2 Race, R R Sanger, R Blood Groups in Man Oxford, 1954
3 Wiener, A S *Bull Wld Hlth Org* 1950 3 265
4 Fisher R A, Race, R R *Nature, Lond* 1946, 157, 48
5 Race, R R *Ibid* 1944 153, 771

ntibodies only Every gene of the system seems to be ssociated with a selection of three antigens from these three airs" In his table CDE, CDe, and so on are listed under he heading "genes"

Not all "most likely genotypes" involve high possible rrors, and some can be determined with complete or almost omplete certainty It is well recognised which are subject o error, and how big that error may be Dr Wiener's implied ccusation of recklessly incurring errors of 15% is therefore njust

Probably the only way of differentiating two linked antiodies from one cross reacting one would be the neutralisation f one component with a soluble antigen if this should ever ecome available The distinction between the names of linked nd mixed antibodies can easily be made by the use of brackets —e g , anti ($C+C^w$) but anti $C+D$

The concept of "blood factors" has not been proved, and s not fundamental CDe can quite easily mean an agglutinogen ontaining the three blood factors C, D, and e, and it contains o more characters than its equivalent Rh_1 In Race's original paper C, D, E, c, d, e are in fact considered as possibly being partial antigens, so here again the nomenclature is independent of theory What does it matter to an obstetrician whether his patient is sensitised to part of an Rh_1 molecule or to all of a D molecule ?

In his last paragraph Dr Wiener appears to overlook one thing Most leading workers have previously used (and been proficient in) his terminology, but have abandoned it in favour of CDE Unlearning *his* terminology, therefore, is neither difficult nor painful

AMMONIA METABOLISM AND HEPATIC COMA

SIR,—Your leading article of March 23 gave an excellent résumé of current information on the association of ammonia metabolism and the pathogenesis and treatment of hepatic coma

We were particularly interested in your comments about the use of intravenous arginine in the therapy of ammonia intoxication The stimulus for our use of this agent came from Dr Santiago Grisolia, of the McIlvain Biochemistry Laboratories, his suggestion for its use being based on current knowledge of enzymatic reactions Our clinical results from this starting-point have been most rewarding Since you expressed doubt as to the mechanism of action of arginine, I would like to outline briefly our concept of its function

It has become a fundamental principle of enzymatic reactions that given standard conditions the addition of increasing amounts of substrate increases the reaction velocity in a non-linear fashion This principle has been set forth in the classic Michaelis Menten equation A maximum velocity of course is reached wherein the enzyme is saturated with substrate, but this state is seldom reached in the human body Applying this principle to the removal of ammonia as urea via the ornithine citrulline arginine cycle, the addition of any of these substrates should increase the reaction velocity and therefore increase the removal of ammonia as urea The cyclic nature of this series of reactions allows enhancement of the entire urea synthesis by addition of only one of the substrates Greenstein and his co-workers, at the National Institutes of Health, have shown that arginine is the most effective of the agents tried, although ornithine will protect animals from ammonia intoxication when given in amounts three to four times that of the arginine necessary We feel that the effectiveness of arginine is due to the free permeability of arginine into the liver cell and also the high concentration of arginase in the liver The arginine therefore acts as a precursor of ornithine in the urea cycle and is more effective owing to its relatively more easy access to the enzyme system

We feel, as you do, that the most important measure in the treatment of hepatic coma is the complete removal of all protein from the diet, gastro-intestinal tract, or any other source Gastro-intestinal sterilisation is certainly an important adjunctive therapy Our clinical results with arginine, however, have left little doubt in our minds that it is a most important addition to the therapeutic regimen, particularly in getting the patient out of coma rapidly

ROBERT T. MANNING

HOSPITAL INFECTION

SIR,—In your leader last week you state that the general frequency of infections is not known Actually, an index is the frequency of infection of "clean" surgical wounds—e g , orthopædic and hernia incisions These should all heal rapidly and without infection If any are infected, the facts are reported at once and the cause is investigated

It is only too true that ideas on cause and prevention have fluctuated rather than progressed This lack of progression is not due to lack of knowledge but to lack of interest and lack of intelligent application of knowledge

The view that "drastic measures taken to quell outbreaks are unnecessary in the ordinary way" is only too popular There is no doubt that reports of hospital infection are prompted by unusually great amounts of infection and by a laudable desire to acquire merit for successful remedial measures Some of these successful remedial measures have passed into routine, after the crisis was overcome—a very praiseworthy decision On the other hand, "The Devil was well, the devil a Saint was he!" often applies

You suggest that "before any real progress can be made the precise frequency of hospital infection of all types in medical, surgical, and obstetric units up and down the country must be ascertained" Surely, the question of dealing with these problems would not arise if the problems did not already exist, in formidable array I submit that a good deal is now known of the frequency of hospital infections

The suggestion that skin carriers of pathogenic organisms might be specially liable to wound infection is a most interesting one, and I am sure that they are specially liable

The work of Williams and others in the Air Hygiene Laboratory at Colindale is important, most hospitals would welcome an investigation on the lines you suggest Very few hospitals have a slit sampler or a statistician Statisticians might be better employed in cutting down expenditure in hospitals than in aiding research

To mention only a few factors concerned in infection in hospitals that have been dealt with recently in published reports contaminated thermometers,[1] baths,[2] noses,[3] fingers,[4] umbilical cords,[5] fomites,[6] blankets,[7] pillows,[8] mattresses,[9] floors,[10] dust,[11] septic wounds,[12] and plasters,[13] and patients with infectious diseases, sometimes admitted undiagnosed or during the incubation period [14]

Investigation of the bacterial contamination of air in hospitals has much to recommend it, but it cannot be the whole answer to the problem Effective measures can be instituted with the knowledge that we now have

Liaison between Hospital and Practitioner

Disclosures at a recent inquest[1] suggest that there may be need for closer liaison between hospital and general practitioner in cases where the patient is attending an outpatient department

The inquest was into the death of a young man, aged 17, by barbiturate poisoning

Last October he had complained to his doctor of tiredness and of sleeping too much After he had seen a physician, it was suggested that the cause was mental and in January he was admitted to hospital He appeared to do well and was soon discharged, thereafter attending three times as an out patient He was given a tranquilliser to be taken four times a day and 'Tuinal' to be taken at night, he was warned that he must not exceed the dose He also visited his general practitioner weekly and complained to him that he was not sleeping enough, the doctor prescribed paraldehyde in liquid form, and the patient appeared to improve The doctor told the coroner that he would not have prescribed paraldehyde if he had known that tablets had been prescribed at the hospital

A pathologist told the coroner that necropsy had revealed that the young man had taken at least 20 capsules of tuinal in addition to a normal dose of paraldehyde The combination of the two did not have any sinister significance, but normally it would be unwise to give the two at the same time

The acting superintendent of the hospital said that the general practitioner would normally be told that a patient was attending the outpatient department, it would be assumed that the general practitioner would realise that the patient was obtaining drugs from that place "We do not write to the practitioner when they attend In this case one would expect the young man to tell the general practitioner what he was getting" On certain nights the drugs might not give him the desired sleep, and he might take two or three more tablets so that he became intoxicated and might go on taking them without knowing what he was doing He did not think that the patient had suicidal tendencies, or he would not have entrusted him with the tablets

The coroner agreed that the young man did not show any suicidal intent, and returned a verdict of accidental death He said that he was "a little shaken" that there was not more liaison between the hospital and the practitioner, but he had no idea whose fault this might be

Diminished Responsibility

The Homicide Act, 1957, came into force on March 21 Until then, English law knew no defence of diminished responsibility in criminal cases, although it allowed the defence of insanity within the narrow limits of the McNaughten rules Section 2 of the new Act provides that a person shall not be convicted of murder if he is suffering from such abnormality of mind as substantially to impair his mental responsibility, f purpose the abnormality of mind may arise fr arrested or retarded development, (b) any in cause, or (c) disease or injury The section provid in such cases the conviction shall be for manslaug

This new defence was pleaded for the first ti a case at Leeds Assizes last week[1]

Shirley Campbell, a 21-year old coloured mill was charged with the murder of Susan Pickles, aged 17 m While the parents were at the cinema she had been l after the child, who was later found dead with a belt tied the neck Counsel for the prosecution explained th defence and said that he would not resist the defence if Counsel for the defence pleaded the section and called m evidence The jury found the accused not guilty of m but guilty of manslaughter The judge said that this w right verdict on the evidence and sentenced Campbell maximum sentence for manslaughter—life imprisonm

Obituary

JOHN PERCY LOCKHART-MUMMERY

M B Camb, F R C S, F A C S

Mr J P Lockhart-Mummery, consulting surge St Mark's Hospital, London, and for many years c man of the executive committee of the British Em Cancer Campaign, died at Hove on April 24 at age of 82

He was the eldest son of J Howard Mummer Islips Manor, Northolt, and he was educated at School and Caius College, C bridge After taking part the natural sciences tripo 1897 he was appointed assistant demonstrator of a omy in the university continued his medical stu at St George's Hospital, w he won the Thompson medal After qualifying in he held several house-appo ments there and was for a t demonstrator of operative su ery In 1900 he took F.R C S and soon afterwards joined the staffs of the No East Hospital for Children Hackney and the King Edw VII Hospital But his appointment in 1903 to St Ma Hospital showed the true direction of his surgical be and the following year he published in our columns important paper on the use of the electric sigmoidosco "The human mind," he wrote in a characteristic fi paragraph, "is so constituted that we always experien a certain pleasure when we have succeeded in obtaini access to some spot hitherto difficult or impossible explore And in medicine and surgery the perfection a method by which we are enabled accurately to expl hitherto inaccessible portions of the human body alwa arouses our interest and helps to perfect our art" 1908 he was awarded the Jacksonian prize of the Ro College of Surgeons of England for his essay on disea of the colon

His writings, his teaching, and his techniques as surgeon drew many visitors from abroad to his operatin theatre, and the reputation of the hospital and the you specialty of proctology grew with his own In 1913 was the first secretary of the British Proctological Socie and it was largely through his guidance that the societ after a period as a subsection, became in 1939 an ind pendent section of the Royal Society of Medicine I interest in cancer research led him to become one of t founders of the British Empire Cancer Campaign, t first chairman of its executive committee, and for ma years the editor of its annual reports

But despite the claims of hospital, private practice a committee work he found time for a great deal of writin and he continued this art with pleasure after he h relinquished surgery

[1] *Times*, April 27, 1957

O E D writes·

Lockhart Mummery had " the pen of a ready writer " and his literary output was truly remarkable as a glance at his bibliography in the *Collected Papers of St Mark's Hospital* shows This centenary volume was published in 1935, when Lockhart Mummery was sixty years of age, and up to that time he had written 6 books, *made major contributions to* 6 other standard textbooks, and published 163 papers in scientific journals During his last five years of hospital work, he wrote another 20 papers After retirement he turned from medical and scientific subjects to writings of a more speculative character which gave scope to his vivid imagination In these he sometimes gave the impression that the subject was running away with him, but his writings were always interesting and original, for he could never be dull

One of his most appreciated contributions was his small handbook, *The After Treatment of Operations* (1903) This ran through four editions, became widely known outside this country, and was eventually translated into Arabic, which gave him much pleasure His larger textbook, *Diseases of the Rectum and Colon*, was almost equally well known It was profusely illustrated, and he pointed out in the preface to the second edition in 1934 that a new feature had been introduced by using photographic reproductions of actual operations to illustrate operative technique He was a keen photographer and worked with enthusiasm to surmount the technical difficulties of those days so as to obtain photographs of operations which might be good enough for reproduction as book illustrations

Cancer research always made a strong appeal to him, and despite the many other claims on his time he made strenuous efforts to keep abreast with it in all its aspects Always a [illegible]uded opinion, in the early 'thirties he made up his [illegible] cancer was best explained as due to a somatic [illegible] in 1934, in *The Origin of Cancer*, he set out

brought all the needed qualities to the task of ensuring that there was one single unit of strength for each important substance which could not be chemically assayed, and that this unit was recognised and accepted throughout the world To him more than to any other man is it due that a ship's surgeon, for instance, can replenish his stock of diphtheria antitoxin or streptomycin in any part of the world knowing that the units marked on the package are the same units that he dealt with in his home port Though Gautier in his work for the League of Nations had from time to time other and wider interests than biological standardisation, one of his happiest moments was when, before the war had ended, he met old friends at a meeting in London to standardise penicillin He had the physique of a rugby forward, and his bustling, somewhat extrovert, manner might give a first impression of sound without substance But his technical knowledge and personal shrewdness made and kept him indispensable through 30 years of kaleidoscopic changes in the world of international health

MAUD MARY CHADBURN

O B E , M D Lond

THREE London hospitals owe much to Miss Chadburn She served the Elizabeth Garrett Anderson Hospital as a surgeon for 20 years, and only resigned in 1922 because she believed that the time had come when women patients should have greater opportunity of consulting women doctors This belief inspired her work in founding and serving the South London Hospital for Women and later the Marie Curie Hospital

She was born in 1868, the daughter of the Rev James Chadburn, and she studied medicine at University College and the London School of Medicine for Women After qualifying the whole answer to the problem Effective measures can be instituted with the knowledge that we now have

Lockhart-Mummery had " the pen of a ready writer ' and his literary output was truly remarkable as a glance at his bibliography in the *Collected Papers of St Mark s Hospital* shows This centenary volume was published in 1935 when Lockhart-Mummery was sixty years of age and up to that time he had written 6 books made major contributions to 6 other standard textbooks, and published 163 papers in scientific journals During his last five years of hospital work he wrote another 20 papers After retirement he turned from medical and scientific subjects to writings of a more speculative character which gave scope to his vivid imagination In these he sometimes gave the impression that the subject was running away with him but his writings were always interesting and original for he could never be dull

One of his most appreciated contributions was his small handbook, *The After Treatment of Operations* (1903) This ran through four editions, became widely known outside this country, and was eventually translated into Arabic, which gave him much pleasure His larger textbook, *Diseases of the Rectum and Colon*, was almost equally well known It was profusely illustrated and he pointed out in the preface to the second edition in 1934 that a new feature had been introduced by using photographic reproductions of actual operations to illustrate operative technique He was a keen photographer and worked with enthusiasm to surmount the technical difficulties of those days so as to obtain photographs of operations which might be good enough for reproduction as book illustrations

Cancer research always made a strong appeal to him, and despite the many other claims on his time he made strenuous efforts to keep abreast with it in all its aspects Always a man of decided opinion, in the early 'thirties he made up his mind that cancer was best explained as due to a somatic mutation , and in 1934, in *The Origin of Cancer*, he set out the theory that cancer arises as the result of a mutation of somatic cells leading to more rapid growth He preached this doctrine with fervour for the latter years of his working life, but was a little disappointed in the amount of attention the book received

On the other hand he had no reason to complain that his earlier work was disregarded and he had the satisfaction of seeing his advice and teaching widely adopted His classical description of the operation of perineal excision of the rectum for cancer was published in these columns in 1920 and his pioneer observations on familial polyposis in 1925 The latter paper initiated a research into the incidence and inheritance of familial polyposis which has been continued with the aid of a grant from the British Empire Cancer Campaign ever since Lockhart Mummery continued to take an interest in this long after he had left the staff of St Mark s Hospital and it was a source of pride and satisfaction to him when his son was appointed to the staff of the hospital

RAYMOND GAUTIER

Dr Gautier, a former assistant director-general of the World Health Organisation and research director for the International Children's Centre in Paris, died last month at the age of 71

He was born in Geneva and qualified in 1911 He was on the staff of the university laboratory of physiology and of the Institute of Hygiene and Bacteriology at Geneva before he joined the Health Organisation of the League of Nations in 1925 as head of its section of biological standards The following year he was appointed director of its Eastern office at Singapore, where he took a large share in controlling the cholera epidemic of 1928 In 1930 he returned to Geneva and continued his work on biological standardisation till in 1938 he was appointed acting director of the Health Section of the League of Nations Towards the end of the late war he was often in Washington and London discussing and organising health measures for the liberated countries In due course he became deputy to Dr Brock Chisholm on the Interim Commission of W H O and later in W H O itself After he retired at the age of 65 he went to Paris to resume his old association with Dr Rajchman at the International Children's Foundation

An old colleague writes

In his particular sphere—biological standardisation—Raymond Gautier was *sans pareil* With a solid grounding in old style hygiene and bacteriology at Geneva University a varied administrative experience and Swiss nationality, he brought all the needed qualities to the task of ensuring that there was one single unit of strength for each important substance which could not be chemically assayed, and that this unit was recognised and accepted throughout the world To him more than to any other man is it due that a ship's surgeon, for instance, can replenish his stock of diphtheria antitoxin or streptomycin in any part of the world knowing that the units marked on the package are the same units that he dealt with in his home port Though Gautier in his work for the League of Nations had from time to time other and wider interests than biological standardisation, one of his happiest moments was when before the war had ended, he met old friends at a meeting in London to standardise penicillin He had the physique of a rugby forward and his bustling, somewhat extrovert, manner might give a first impression of sound without substance But his technical knowledge and personal shrewdness made and kept him indispensable through 30 years of kaleidoscopic changes in the world of international health

MAUD MARY CHADBURN

C B E , M D Lond

THREE London hospitals owe much to Miss Chadburn She served the Elizabeth Garrett Anderson Hospital as a surgeon for 20 years, and only resigned in 1922 because she believed that the time had come when women patients should have greater opportunity of consulting women doctors This belief inspired her work in founding and serving the South London Hospital for Women and later the Marie Curie Hospital

She was born in 1868, the daughter of the Rev James Chadburn, and she studied medicine at University College and the London School of Medicine for Women After qualifying in 1893 she held house-appointments at the Royal Free Hospital Clapham Maternity Hospital, and the Elizabeth Garrett Anderson Hospital Later she became curator of the museum and surgical registrar at the Royal Free In 1898 she took the degree of M D , and in 1903 she was appointed to the staff of the Elizabeth Garrett Anderson Hospital Very soon she had a large and successful practice in general surgery and in gynæcology for during most of her professional life women surgeons usually did not separate these two specialties At different times she ran two large nursing-homes for her private practice Hospital and private patients alike gave her implicit trust and it is recorded that one went so far as to say " If Miss Chadburn said I was to have my head cut off I should agree '

But her chief work was the South London Hospital for Women which in its early days was so largely dependent on her initiative, courage and foresight A colleague who joined her there in 1916, describes its steady growth

At first we saw outpatients in converted houses near the Elephant and Castle A large house at Clapham Common which was to have been converted for hospital purposes was being demolished and instead a modern hospital built with money derived from anonymous donors' largely through Miss Chadburn s enterprise In the years that followed large properties to the left and right of the new block were incorporated and the number of beds rose from 30 to 260

Miss Chadburn also played a big part in the foundation of the Marie Curie Hospital to which she was surgeon For many years she was chairman both of its medical committee and its research committee In 1931, to mark her retirement from her hospitals she was appointed C B E She was a past president of the London Association of the Medical Women's Federation Despite these heavy professional responsibilities which she had willingly accepted and which she gener ously fulfilled, she also adopted three children whom she brought up and educated

A H B writes

Miss Chadburn's pre eminence was as a practical surgeon She left a tradition of slow, gentle surgery, which gave very good results She was held in high esteem by her colleagues at all her hospitals, but she was not a public figure, and she did not publish reports of her work Only those closely associated with her knew what a remarkable woman she was, and how much was accomplished by her quiet persistence *She was indefatigable, and could spend long hours in the* operating-theatre without strain Those who assisted her in her heyday recall operating sessions which went on through the evening, perhaps into the night Everyone else might flag—but not Miss Chadburn ! She was rather small and without an obviously forceful personality , yet her deceptively mild manner masked an indomitable will power, as those who worked with her on committees well knew She had a long life, and died at the age of 89 on April 24, in the hospital where she had first come as a house surgeon To the end she retained the dignity and quiet charm of manner which distinguished her

Dr G R. MATHER CORDINER

F R B writes

It would be a pity if Dr Cordiner's generous and ready acknowledgment of the help which he had received from the work of Forssell, Akerlund, and Berg were to prevent recognition of his own contributions to gastro intestinal radiology Although the perfection of his technique and the accuracy of his interpretation were clear for all to see, only those who were trained by him could assess his pioneer work, because he published relatively little They saw him in his moments of hesitation when he was trying to assign the exact significance to some particular X-ray finding , there was no book on earth that could help him at these times , this work was absolutely original Too much emphasis has undoubtedly been placed on the use of compression in the techniques which he used, and it is not generally known that he was the greatest advocate of the use of gravity in the demonstration of lesions of the stomach and duodenum The tilting tables which he designed before the late war have never been bettered—in fact a return to many of the features of his original apparatus would be an advantage As long ago as 1936 he showed me the first chapter of his book on the radiology of the gastro intestinal tract—a book that, alas, has never been published The reasons for this were many, among them the war and the difficult times which have followed it Perhaps another reason was his passion for accuracy and exactness in everything He could not bear to think of something being published that was not precise A less busy man would have had time to polish his work , Dr Cordiner never found time to fashion the book to his own liking Much of his work was concerned with rather unrewarding and controversial diseases such as gastritis, duodenitis, and inflammatory changes in the kidneys These diseases are not yet wholly understood and the value of his contributions cannot yet be assessed

Only those who worked for Dr Cordiner could fully appreciate his untiring energy or realise the extent to which he drove himself in the pursuit of his work The last years were undoubtedly a tremendous strain on his health and he could never have continued without the devoted affection and help of his wife

---

Mr A H Coughtrey, librarian of St Bartholomew's Hospital Medical College from 1903 to 1939, a vice-president of the Institute of Hospital Administrators, and a former editor of the *Hospital*, died on April 18 at the age of 82

Births, Marriages, and Deaths

BIRTHS

ELITHORN —On April 28 at University College Hospital, to Dr Helen (Wendy) Grant wife of Dr Alick Elithorn—twins, Justin Richard and Sandra Clare

Notes and News

APARTHEID IN MEDICAL EDUCATION AND NURSING

LAST week we summarised a statement by vice-chancellors and principals of universities and university colleges in this country expressing concern at recent developments in South Africa Similar concern, grave enough to override personal political convictions, is seen in a unanimous resolution of the South African Medical Council [1] This council, which was not consulted about the proposed transfer of the Durban Medical School from Natal University to State control, has unanimously adopted a resolution which says

> "It has been brought to the notice of the Council that a new method of control of education is envisaged for the Durban Medical School and that there is a possibility that this may lead to a new pattern which may not be acceptable to the Council for purposes of training of medical practitioners
>
> "As a statutory body the Council has grave responsibilities in regard to medical education In order to obviate unforeseen difficulties which may arise at some future date when the standards are to be considered and the facilities, School and examinations inspected, the Council respectfully suggest to the Minister of Education and of Health to take the necessary steps prior to enacting the legislation now before Parliament to have the implications as they affect the responsibilities of the South African Medical and Dental Council further investigated and reported upon"

Under the government's Nursing Bill [2] the Nursing Council of South Africa would be an all white body, separate races would have separate sections in the Nursing Association, and separate registers would be kept A fine of up to £200 is prescribed for anyone allowing a white nurse to work under a non white person in any hospital or similar institution or training school

CLERKS IN THE WARDS

LAST autumn four part-time clerks were appointed at the Ipswich and East Suffolk Hospital to relieve the ward sisters of clerical work and allow them more time for other duties The Ipswich hospital management committee reports [3] that the first six months of the experiment have been successful The ward sisters say that the clerks have been of "enormous help" and the matron thinks that the sisters are 'working under less strain"

CEREBRAL PALSY

LAST October, the British Council for the Welfare of Spastics held a conference at Birmingham on cerebral palsy, presided over by Prof J M Smellie A booklet combines the four admirable addresses then given [4]

It is hard to imagine a better account of the clinical picture than that given by Prof R S Illingworth He mentions the dangers of large doses of vitamin K in the newborn through hæmolysis leading to kernicterus, and this subject was among the many dealt with in Dr Frances Braid's talk on the ætiology of cerebral palsy Dr H M Cohen surveyed the scholastic needs of affected children, with illustrations from the practice in Birmingham, and Mr A Innes, F.R C.S, spoke on their management He emphasised how gross are the cerebral lesions in many cases, and discussed methods of treatment including physiotherapy and orthopædic and neurological surgery

HEALTH EDUCATION

A Ministry of Education publication,[5] modestly styled a "pamphlet," contains much good matter, excellently expressed, on the subject of health education. The anonymous author adds knowledge of English literature to that of his subject, and sympathy and imagination to both The result is stimulating instructive and pleasant to read The main thesis is that health education should arise from and be a part of almost all school subjects—history, geography and literature no less than the sciences, that ad hoc detailed and dogmatic "health instruction" is of limited usefulness and that example and practice are as important as precept Part 1 expounds this theme, and part 2 deals with the hygiene of body and mind and the prevention of preventible diseases An admirable chapter on normal development, from the report of the committee on maladjusted children forms an appendix

Flaws are few, but might not the young be dissuaded from smoking in terms more vigorous than those of the late Minister of Health ? Ought not all little girls to have rubella and why does choral singing find no mention as an unrivalled exercise for the spirit, the intellect, and the respiratory organs ?

RADIOLOGICAL UNITS AND MEASUREMENTS

THE 1956 recommendations of the International Commission on Radiological Units and Measurements have been published as a handbook [1] and replace the Commission's 1953 report [2] The new report includes basic information and data necessary to make radiation-dose measurements in energy units (rads), and to convert data expressed in röntgens to the equivalent in energy units

The comprehensive account of radiological quantities, units, and symbols includes a discussion of the parameters involved in the various definitions Guidance is given on the clinical application and physical aspects of absorbed dose measurements—for example, methods of calculating absorbed dose from measured ionisation The results of several recent international comparisons relating to both X rays and radioactivity are described A suggested outline of an international treatment summary form is given in one of the appendices

University of Durham

The honorary degree of D C L is to be conferred on Sir John Stopford, F.R S

At a special congregation to be held during the meeting of the British Medical Association in Newcastle upon Tyne the honorary degree of D C.L is to be conferred on Dr A H. Hall and Dr S Wand of D SC on Prof G W Pickering and of M.D on Dr Mona Macnaughton

University of Glasgow

On April 27 the following degrees were conferred

M.D—A. S Douglas (with honours)
M.S—J W Sutherland (with honours)

On June 19 the honorary degree of LL.D will be conferred on Brigadier J S K Boyd, F R.S, and Sir James Paterson Ross

Society of Apothecaries of London

Sir Henry Dale, O M, F.R S, will deliver the Gideon de Laune lecture on Tuesday, May 14, at 5 30 P M at the hall of this society, Black Friars Lane, E C 4 His subject will be Medicinal Treatment—its Aims and Results

At recent examinations the following were successful

L M.S.S.A—D L Oldfield J L. Currah W A Garson, S H. Thomas M L A. B Bancilhon M J Allan A F Broad, R E Owen A T Darko R C Snelling J H Kendall A G Snart C Bell G A Robson R J L Potts K C Kewish R Owen

D.I.H—D E Marchant C C Molloy, F H Pratt J D Walters

British Society for Immunology

A meeting of this society will be held at the Westminster Medical School, Horseferry Road, London, S W 1, on Friday and Saturday, May 10 and 11, starting at 10 30 A M The programme includes a symposium on non specific immunity, when Prof A A Miles will take the chair

Calouste Gulbenkian Foundation

In this Foundation's first list of grants it is announced that Dr H L Glyn Hughes, retiring senior administrative medical officer of the South East Metropolitan Regional Hospital Board, has been invited to survey the needs of homes for the dying in Great Britain It is explained that these homes, most of which are religious foundations, provide for a need, spiritual as well as medical, not always adequately met by hospitals of the National Health Service

Rockefeller Foundation Grants

During the first quarter of 1957 the Foundation distributed $2 700 000 Grants for medical education and public health amounted to $550,000, and for biological and medical research to $810,000 The grants include

> $36 000 to the University of Cambridge for research equipment for the school of biochemistry £10 000 (over the next two years) to the University of London in support of Prof J Z Young's research at University College on the structure and functioning of the brain and $12 000 (over the next three years) to University College Dublin to help Prof E J Conway to continue his research into the process of accumulation and exchange of inorganic ions in cells and tissues

Royal College of Physicians of London

At a comitia held on April 25, with Dr Robert Platt, the president, in the chair, the following were elected to the fellowship

M M SUZMAN Johannesburg, J L H EASTON, Bedford, P C C DE SILVA, Colombo, CHISHOLM MCDOWELL, Remuera New Zealand, A B STOKES, Toronto, MARTIN HYNES, London, OSWALD SAVAGE, London E C O JEWESBURY, London, F J W MILLER, Newcastle upon Tyne G W BODEN London, ARTHUR LEESE, Leeds, J N MORRIS London J H BOLTON, Melbourne, W R S DOLL, London G M KOMROWER, Manchester, I M ANDERSON, London, R B EVANS, Cardiff, J C GILSON, Penarth, Glam, P L MOLLISON, London, WALTER SOMERVILLE, London, C D NEEDHAM, Aberdeen, J M MALINS, Birmingham, N D COMPSTON London, J F GOODWIN London A G LEATHAM, London, W D BRINTON, Winchester, Hon D A P ANDERSON, Reading, E J MOYNAHAN, London, J M LEDINGHAM, London J A SCOTT, London, P M F BISHOP, London, J H BIGGART, Belfast, R F LOEB, New York, J R PAUL, South Carolina

The following having satisfied the censors' board were elected to the membership

L J H Arthur, M B Camb, J H Baron B M Oxfd, N M Bleehen, B M Oxfd, D R Coles, M B Brist J M Duggan, M B Sydney, Howard Duncan, M B Sydney, D A W Edwards, M D Camb, J S Garfield, M B Camb, J M Greenaway, M B Sydney, Laurence Henry, M B Birm, T H Hughes Davies B M Oxfd, Marcel Kinsbourne, B M Oxfd, Joyce J P Lomas, M D Lond, P J Maloney, M B Sydney I D Melville M B Glasg, Paul Mestitz, M B Lond, Marion B Morton M B Sydney, I B Munro, M B Glasg Abul Khayer Muhammad Nawab Ali, M B Calcutta, J R Officer, M B Melb, A M Parfitt M B Camb, Jane Platnauer, M B Lond, Stanley Shaldon, M B Camb, D H Trapnell, M B Camb, Mary P Wilkinson, M B Lond, R T Williams, M B Camb, B W Windeyer, M B Sydney

Licences to practise were conferred on the following 165 candidates who have passed the final examination of the Conjoint Board

Peter Abraham, Leslie Adamson, Mary M Adlington D R Amies, R St J Angel, J R Anthony G J L Ardouin, B R Baker, M A Barraclough, Gerald Bevan, D P Birkett, B D Birt, Sybil Birtwistle J L Booth, Anne Bromley Godfrey Brooke, R J A Brown, J A W Buckley, T M Bull, P G Burles, J L Canter, P B Carpenter Margaret T Challis, J A Chalmers, Zoe D Chamberlain, T D Cochrane, Joan R Colston, Christina M Comty, Phoebe M Cotes D R Couchman, J M R Cox, Dorothy Cullen D W Davies Patricia W R Daymond, J M Dunison, D M Dingle, B C Dixon Warren, A B Dunderdale M J Dyer, Joan M Edwards, P J Edwards, B J Ellam M K El D H El Rifi Pauline M Feavers, J S Ferguson, Ann L M Field, Elizabeth C Finn, P S Firth, G N Flaherty, Evelyn C Foot, J A Fox G G Francis P I Frank, R G G Gain, Ann F Gamble, R D Gardner, J C Garnham, W H S George, Jeremy Goodchild, Pamela J H Goodwill, M S Gottlieb J H C Gough Judith F Gould, J N Graham Evans, June S Grant David Greenwood, Olive M Grundy, Jack Hajioff, Ahmed Hakki J G Hall, T J Hall James Halls D L Hamblen, V J Hartfield Sally Haynes, M R Heal, R C Hicks, L M Hillman L J Hobbs, Margaret B Howell, P J W Howes, S W Hyams E E Inyang, J D Jowitt A C Kaeser, B R Kesby, M S Kessel, K C Kewish, D W Keys, R M Kinsey J O Knowles, M I Lander, M J Lavine, D J Lawson, D H Lawton J K Lawton F I Lee, Eva H Letchner, G C Liddle, Helen A Linn, D B Longson Mary K Lucas Gillian B McCullagh, M J McLoughlin, B C Mallaband, E C Marsh, Nancy E V Matthews, P A Mead, Katherine M Moore, R V Morris, K A A Mourin, R C Mulholland Elizabeth M Nicholson, K F O'Sullivan D W Owen, R E Owen, D W Patient, Sylvia J Pinder, M A Pratelli, V J Pratt, V M Rakoff, Rudra Rasaretnam, Savino Ravetto, R L Raymakers, P R Riddle, E O Roberts, Michael Roburn Marita R Rodan Christine A Rodgers H D Rogers, J E Rogers Muriel E Rolfe, K W Rowden, D H R Salter, Marie Luise B Seidler, H G S Sergeant, Mary Sibellas, S H Simonian, G B Smith J L Storey, P E N Suter, A R Taylor, M F Terry, C R Thomas Edith H Thomas, C D Thompson D F J Thompson I G Thomson, Janet E Timberlake J A D Walkden M P Walsh, R R Watkin, D M Wayte Felice M Weber, G T Whitfield William Whitrow, Anne M Wigley, F R Wilkes, R P Williams, Wadad Williams, Anne M Wilson, E H Wisely B E M Wright, Margaret E G Wright, G B Wyatt

The following diplomas and those mentioned in our issue of April 20 (p 846) were conferred jointly with the Royal College of Surgeons

D C H—B K North, J N Rea

Endocrine Aspects of Breast Cancer

The University of Glasgow is holding a conference on this subject from July 8 to 10 The topics chosen for discussion include the endocrine ablations and their effects, endocrine aspects of experimental breast tumours and hormone dependence in human breast cancer

Natural Childbirth Association of Great Britain

This association, lately formed with a lay committee, wishes to get in touch with pædiatricians, pathologists, and obstetricians who are interested in natural childbirth and who may be able to undertake research into the causes of stillbirth and infantile mortality and morbidity The association's offices at 44, Great Russell Street, London W C 1

National Birthday Trust Fund

Prof Stanley Walton is to speak at the annual meeting of this fund at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2, on Tuesday, May 7, at 3 30 P M

International Congress on Proctology

The Argentinian Society of Proctology is organising this congress, which will be held at Mar del Plata from Dec. 1 to 8 The speakers will include Mr W B Gabriel and Mr Rodney Maingot

Hospital Authorities and Staff Management

The Royal Institute of Public Administration will hold a conference on this subject at the Royal Empire Society, Craven Street, London, W C 2, from May 20 to 22 Further particulars may be had from the director of the institute, 67A, New Cavendish Street, W 1

British Dietetic Association

The dinner of this association, with the Nutrition Society, will be held at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2, at 7 15 P M on Friday, May 3 On Saturday, May 4, a scientific meeting will be held at Queen Elizabeth College, Campden Hill Road, W 8, at 9 30 A M, to mark the 21st anniversary of the foundation of the association Dr B Bronte Stewart will speak on natural and processed vegetable fats and their effects on health, and Prof R E Tunbridge on diabetes mellitus

Club for Disabled Children

The Wingfield Music Club was formed in Walthamstow, London, two years ago to help disabled children by teaching them music Among their members they have children with poliomyelitis, spastics, and amputees The club is entirely voluntary, and the teachers try to interest children in instruments best suited to their disability Thus a child who can raise its hands above its head can be taught the violin, one who cannot will be taught a wind instrument Three of the children have taken the second and third examinations of the Associated Board of the Royal School of Music The club has now an orchestra of thirty, which has given two public concerts and is holding a third on Sunday, May 19, at Lloyd Park, Forest Road, E 17, at 3 30 P M Further information may be had from the secretary of the club, 50, Belle Vue Road, E 17

Dr Leonard Browne has been elected vice chairman of the London County Council

Mr Hermon Taylor is to visit the United States this month to speak at the annual meeting of the American Gastro enterological Association in Denver, Colorado He will also address the American Gastroscopic Society who have given him the Schindler award

From the Rockefeller Institute, New York, N Y

THE rôle of unsaturated fatty acids in human nutrition is a topic of rapidly increasing popularity in both scientific and lay publications It has been claimed that ingestion of this group of fatty acids decreases the concentration of lipids in the serum and that an inadequate intake of these acids may be the cause of the high serum-lipid levels so prevalent in Western civilisation Since these high levels are allegedly involved in the pathogenesis of arteriosclerosis and coronary disease, it has been tempting to implicate lowered intakes of unsaturated fatty acids in the rising incidence of these diseases Although existing experimental data do not as yet warrant such conclusions, there is mounting evidence that the precise chemical composition of ingested fatty acids, in particular the degree of saturation, may have considerable significance in both health and disease (Sinclair 1956)

A number of experimental observations indicate that saturated and unsaturated acids are not metabolically equivalent, as previously assumed

1 Burr and Burr (1929) demonstrated that certain polyunsaturated acids cannot be synthesised by rats, and that diets devoid of these acids produce a distinctive deficiency syndrome Since then it has been shown that linoleic, arachidonic, and other acids are essential for many species (Holman 1956) The complete deficiency syndrome is produced only by exclusion of these acids from the diet of growing animals, thus, it is hardly surprising that this deficiency state has never been clearly demonstrated in man

2 The turnover-rate of unsaturated acids is slower than that of saturated acids in rat liver and rat carcass (Pihl et al 1950), suggesting differences in the metabolic pathways of these two groups of acids

3 Studies of the structure of natural lecithins show unsaturated acids to be preferentially esterified at the alpha carbon of glycerol (Hanahan 1954), whereas most triglycerides are built with these acids esterified in the beta position (Mattson, personal communication) Such structural differences indicate different metabolic pathways

4 Enzymatic esterification of cholesterol in the intestinal lumen is more rapid with unsaturated fatty acids than with saturated acids (Swell and Treadwell 1955) Another relationship of essential fatty acids to cholesterol metabolism has recently been pointed out (Alfin-Slater et al 1954)—i e, that in the rat deficient in essential fatty acids the content of cholesterol esters in the liver is greatly elevated but serum-levels are decreased Peifer and Holman (1955) have shown that this deficiency state in rats can be accelerated by feeding cholesterol in the fat-free diet Since the cholesterol of serum is preferentially esterified with highly unsaturated acids (Clément et al 1955), this mechanism may remove these acids from sites where they exert their essential quality (Klein and Johnson 1954)

The most recent stimulus to study in this field comes from clinical investigations which suggest that levels of serum lipids may be related to the dietary intake of unsaturated fatty acids Kinsell and Michaels (1955) found that the feeding of coconut oil (a highly saturated fat) produced higher levels than the feeding of a highly unsaturated oil, soybean oil Long-term feeding tests in this laboratory (Ahrens et al 1955) indicated that serum levels of cholesterol and phospholipids varied inversely with the iodine number of six different dietary fats The findings of these two laboratories were greatly extended in the detailed report by Bronte-Stewart et al (1956) and also were confirmed by the experiments of Beveridge et al (1956)

None of the experiments known to us has proven conclusively that the effect on serum-lipids of these dietary fats is due to the double-bond structure of their fatty acids Nevertheless, there has been widespread acceptance of this hypothesis by workers in human nutrition, and broad applications of the hypothesis have already been made Since we think these extensions premature, it seems appropriate for us to set forth in some detail the studies carried out by us over the past 3 years which bear upon the important questions at issue The unique design of these studies was based on the belief that nutritional experiments can be carried out as precisely in man as in animals In view of numerous well-known differences in species response to nutritional variation, such an approach seemed essential All recognised extra-dietary factors influencing serum-lipid levels were kept to a minimum Patients were carefully selected and then observed within the closely supervised environment of the metabolic ward for periods long enough to assure establishment of equilibrium states Dietary intakes were simplified and rigidly standardised, even the variable of cooking was eliminated Yet all known requirements for essential foodstuffs, minerals, and vitamins were generously supplied Medical and hospital care were provided to the patients without charge, and constant attention was paid to socio-economic factors which might disrupt their adjustment to the study situation Under these circumstances the data obtained have quantitative as well as qualitative usefulness

Methods of Present Studies

In our previous studies (Ahrens et al 1954a) six obese but otherwise normal subjects were fed diets containing 12% of calories as protein and 50% as fat Solid foods made up a large part of the dietary intake At intervals of 6 to 8 weeks, vegetable and dairy fats were exchanged isocalorically without altering other variables Clear-cut decreases in serum-lipid levels were produced when the vegetable fats were fed These findings confirmed and extended the original report of Kinsell et al (1952)

To investigate this effect it was evident that more precise control of the diet was required Accordingly, a technique of oral feeding of liquid formulas was developed (Ahrens et al. 1954b) and has been used almost exclusively in all feeding experiments since 1953 With this method patients were maintained at constant body-weight by suitable adjustment of caloric intake, the proportions of foodstuffs remaining unchanged Changes in body-weight rarely exceeded 1 kg The basic formula consisted of protein 15%, fat 40%, and carbohydrate 45% of total calories There was no source of calories other than the formula Formula feeding has been used uninterruptedly for 36 months in one patient without recognised ill effect, however, in most of the experiments discussed below the feeding tests lasted 4 to 6 months Thirty-eight of forty patients were observed continuously under strict metabolic-ward conditions, four of the forty were sufficiently motivated and intelligent to follow the regimen at home Iodised salt (2 g sodium chloride with 200 µg potassium iodide),‡ 2 multivitamin capsules, and ferrous gluconate (0·3 g.) were given daily as supplements. The entire protein intake was derived from milk proteins; the intake of nitrogen and pattern of amino acid intake were considered completely adequate for adult men and women (Rose et al. 1955).

† Now at University of Lund, Lund, Sweden

‡ We are indebted to Dr Clayton Rich Rockefeller Institute Hospital, for demonstrating a requirement for supplemental iodine in our patients maintained solely by oral formula feeding Unpublished serial radioactive iodine studies showed significant increases in uptake in some patients in less than one month.

The subjects of these studies were hypercholesteræmic or hyperlipæmic patients (some with clinical evidence of arteriosclerosis and xanthomatosis) and normocholesteræmic patients with arteriosclerotic heart-disease. Table I lists the pertinent clinical data. All patients were free from conditions which might complicate the interpretation of long-term metabolic studies, such as renal, hepatic, endocrine, or infectious disease, or nutritional deficiencies. All were ambulatory. Patients with cardiac decompensation were considered ineligible for these studies because of our dependence on daily measurements of body-weight as an index of energy balance.

In addition to routine clinical tests, weekly measurements were made of total and free serum-cholesterol (Sperry and Webb 1950), total serum-lipid phosphorus (Stewart and Hendry 1935), and total serum lipids (Ahrens et al. 1954a). Cholesterol esters and serum triglycerides were calculated from these basic data; generally accepted mean molecular weights for the cholesterol esters (645) and phospholipids (775) were used in these calculations. Rapid determinations of total cholesterol (Abell et al. 1952) made each week checked (within 5%) with the Sperry-Webb values. Studies of lipoprotein changes will be presented elsewhere.

Base-line Levels on Corn-oil Formula

Fig. 1 is a graphic demonstration of the data of a typical feeding experiment. For the first 8 weeks the patient ate ad libitum. After relatively constant levels of serum-lipids had been achieved, formula feeding was begun. In the three succeeding periods, all dietary fat was derived from corn oil, coconut oil, and corn oil, respectively. There were striking decreases in all serum-lipid components during the two corn-oil periods and rises in all except triglycerides when coconut oil was fed. After each change of formula, lipid levels shifted upward or downward in an orderly manner through a 3-week transition phase. This was followed by a new steady state, a plateau of levels marked by only minor fluctuations. Body-weight remained unchanged in all periods.

Not all patients responded to the corn oil formula in the same measure, and only occasional patients with high serum cholesterol achieved normal levels. To compare responses to various dietary fats in different patients, it was necessary to establish in each individual a base line of serum-lipids attained on corn oil feeding. Then, when other fats were substituted isocalorically for corn oil in the basic formula, the serum lipid data obtained during successive steady states could be related to the corn oil base line. Thus, in fig. 1, the level of total cholesterol on the coconut-oil diet was 40% higher than that on corn oil.

Measurements during transitions were, of course, omitted in these calculations. The length of each transition phase was determined on an individual basis by inspection of the assembled data. Transitions varying from 3 days to 8 weeks have been encountered, but, usually, transitions were completed in 2 to 3 weeks. Consequently, with each change in formula at least the first 2 weeks' determinations were discarded; when selecting data for comparative calculations, when transitions were slower, more data were discarded.

It is relevant to define the extent of variation of week-to-week values during that terminal portion of each feeding period designated as the steady state. The duration of the steady state was at least 3 weeks and usually 4 or more. During the steady state the standard deviation of the mean level of total cholesterol, as well as of phospholipids, was less than ±20 mg. per 100 ml. serum in all cases except patient 3, and the pooled variation of the 120 steady states reported in this paper

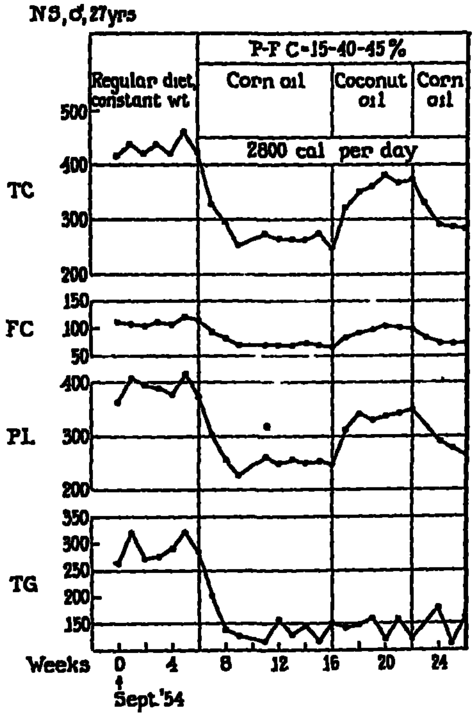

Fig. 1—26 week study of serum-lipids of patient 9, maintained at constant body weight on ad-lib feeding, then by oral formula feeding exclusively.

TC=total cholesterol, FC=free cholesterol, PL=phospholipids, TG=triglycerides—all in mg. per 100 ml. serum. P-F C=dietary proteins, fats, and carbohydrates, as percentages of total calories.

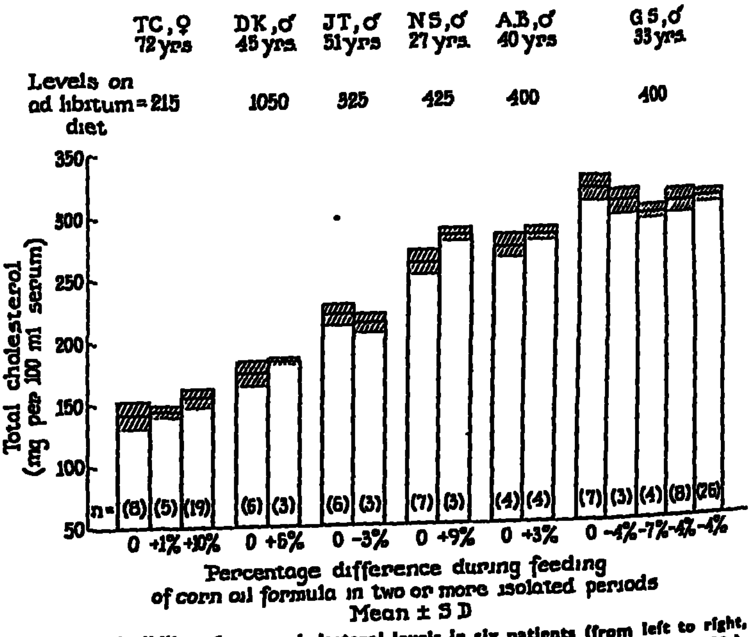

Fig. 2—Reproducibility of serum-cholesterol levels in six patients (from left to right, patients 34, 1, 27, 9, 12, and 13) retested on basic corn oil formula (P-F C=15-40-45%), with other regimens in intervening periods.

Bars show mean levels during steady states, hatched area one S.D. n=number of weekly data during each steady state. Percentage differences along base line calculated with reference to mean levels of first feeding periods.

TABLE I—CLINICAL DATA AND TOTAL SERUM-CHOLESTEROL LEVELS OF PATIENTS SUBJECTED TO BASIC CORN-OIL FORMULA

was ±9 9 mg for total cholesterol, ±4 2 mg for free cholesterol, and ±9 9 mg for phospholipids The deviations of each of these components were unrelated to their total mean concentration Both technical and true biological variations (Watkin et al 1954) of triglycerides were greater than in the case of cholesterol and phospholipids In 95 out of 100 steady states, standard deviations of mean triglyceride levels were less than ±60 mg per 100 ml serum, the pooled variation in these 100 periods was ±31 mg The deviations of triglycerides were larger at higher concentrations of this lipid component, as would be expected from the method of measurement Independent tests showed that about one-third of the total variation of each lipid level could be ascribed to methodological error Differences in mean cholesterol or phospholipid levels of 25 mg per 100 ml of serum are statistically significant at the 1% level, when 4 data are collected in each of 2 steady states under comparison and standard deviations of mean levels are ±10 mg

It is central to the issue under discussion that the concentration of a serum lipid during ingestion of corn oil be a reproducible constant for a given subject The similarity of these levels in re-test periods is shown in fig 2, in which data from six re-tested patients are graphed It is seen that mean concentrations of serum-cholesterol varied by no more than 10% from one corn-oil period to another In the same patients phospholipid levels varied by 7% or less from period to period, but the range of triglyceride fluctuations was as great as 50% In patients 33 and 13 there was no drift of levels during administration of the corn oil formula for 19 and 26 weeks, respectively, as shown by the small standard deviations of values from the mean of these periods Thus, for the period set as a minimum in all our studies (4 to 5 months) the corn-oil base-line remained fixed and showed no "escape"

In view of the fact that serum-lipid levels can be made to vary so strikingly by simple dietary manipulations, little is gained by analysing data obtained during ad-libitum feeding when dietary intakes vary in a complex manner Although data gathered during ad libitum feeding periods are obviously the net result of many undefinable and conflicting dietary forces, such levels are termed "normal" when gathered from patients without manifest illness We made no effort to collect large numbers of such data, although a few determinations of serum-lipids were made during the preliminary work-up of each case Table I compares total serum-cholesterol levels on ad-libitum diets and during maintenance of body-weight on the basic corn-oil formula Decreases of 20% or more were produced in thirty-six of thirty-nine patients during corn oil formula feeding In patient 1 a decrease of 84% was achieved, while a 12% decrease was seen in patient 27, and in patient 15 the corn-oil formula produced no change Excepting these three cases, the percentage decreases ranged from 20–67% (mean 37%, standard deviation ±11%) These data show clearly the unpredictability of response of individual patients to a given dietary fat intake

The Responsible Factors in Corn Oil

Experiments such as that shown in fig 1 suggested that certain factors in the diet raised the levels of serum-lipids, and others depressed them When corn oil was

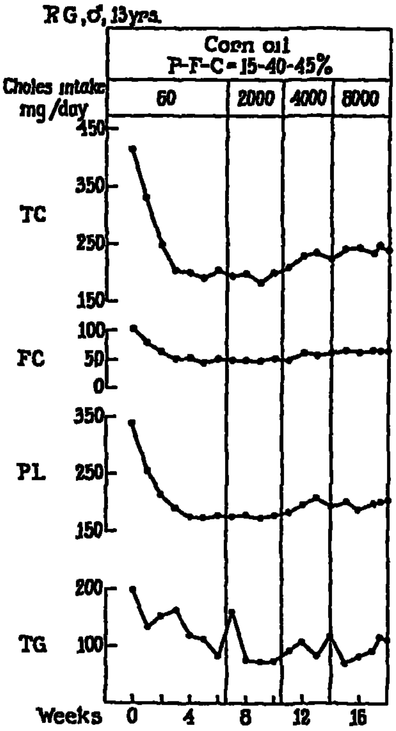

Fig 3—Effect on serum-lipids of additions of cholesterol to the basic corn-oil formula (patient 16) Crystalline cholesterol was dissolved in warm corn oil and homogenised in the formula Increases in cholesterol and phospholipid levels on intakes of 4 and 8 g per day were significantly higher (p< 0 01) than on 0 06 and 2 g per day, but differences were small

fed as the sole source of dietary fat, the lowered levels could have been due to an absence of elevating factors, or to a presence or dominance of depressing factors Since the protein and carbohydrate portions of these formulas were identical, and the total quantity of fat remained constant, the factors in question resided in the qualitative differences between dietary fats

An obvious difference between fats of animal and vegetable origin is the presence of cholesterol in the former and of poorly absorbed plant sterols in the latter However, experiments of the type shown in fig 3 convinced us that the depressions of serum lipid levels during feeding of the corn oil formula were not due to the absence of cholesterol from that formula Similar experiments have been carried out with a lard formula (patient 11), the ingestion of cholesterol (0 6 g per day) with lard produced no higher levels of serum-lipids than lard alone

Corn oil contains 2% or less of its weight as non saponifiable material (sterols, tocopherols, carotenes, hydrocarbons, waxes, phosphatides) About half of this small fraction is mixed sitosterols Therefore, a 65 kg adult maintained on the basic corn oil formula ingests a maximum of 1 g of corn sitosterols per day Experiments were carried out in six patients to whom large supplements of beta sitosterol § (18 g a day) were administered in conjunction with totally vegetarian diets of solid foods In all cases serum-lipid levels were very much higher than when the corn-oil formula was fed These studies indicated that the beta-sitosterol content of corn oil is not chiefly responsible for the depressing effect of this oil on serum-lipid levels

Other feeding experiments were made with oils freed of the major portion of the non saponifiable fraction by both physical and chemical procedures In the first, refined corn-oil was subjected to molecular distillation ‖ A 50 50 cut resulted in threefold enrichment of the non saponifiable material in the distillate fraction and a threefold decrease of this material in the residue Each fraction was fed in the basic formula at 40% of calories, as was the original undistilled oil Serum-lipid levels remained unchanged from period to period in this 17 week test (fig 4), despite a sixfold difference in non saponifiable content in the two distillation fractions Similar studies undertaken by Beveridge et al (1957b) also showed no significant difference in the effects of undistilled corn oil and various cuts of corn oil obtained by molecular

distillation A second experiment was conducted with two fractions obtained in a 50 50 cut of lard by molecular distillation In an 18-week test the lowest lipid levels were reached on formulas containing corn oil (fig 5) Higher levels were found when the two lard fractions were fed (see below), but the feeding of residue and distillate fractions produced no significant differences in levels despite threefold differences in their contents of non-saponifiable materials

The chemical procedure consisted of saponification of the refined corn oil, formation of the insoluble barium soaps, and extraction of these soaps with ethylene dichloride four times to concentrate the non saponifiable materials in the extract ¶ The acids were regenerated and re esterified with glycerol Excess acids and catalysts were washed out before final deodorisation In this process the content of non saponifiable material was reduced from 1 2 to 0 2% Since the reconstructed oil consisted of corn-oil fatty acids arranged at random on the glycerol base, it was necessary as a preliminary control step to show that randomisation of fatty acids did not produce a different effect on serum lipids from that of the naturally constituted corn oil glycerides Therefore, in a 20-week test (fig 6) a patient was fed refined corn oil in the first period, then the same oil after random rearrangement in the second and fourth periods, and the rearranged corn oil poor in non saponifiables in the third period It is seen that the effectiveness of corn oil was not significantly changed by chemical removal of a large portion of the non saponifiable material The lack of effect of randomisation is hardly surprising in the light of previous experiments on digestion and absorption in man (Ahrens and Borgstrom 1956)

Thus, three lines of investigation failed to show that the factors responsible for depressing serum-lipid levels reside in the non saponifiable, non-glyceride portion of corn oil On the contrary, the various lines of evidence suggested that the glycerides themselves contained the sought-for factors Further experiments using fats and oils which varied in fatty-acid composition were carried out in order to test this conclusion

Variations in Fatty-acid Composition

A number of informative tests has been carried out by substituting various natural fats and oils for corn oil in the basic formula These fats were chosen to obtain wide variations in fatty-acid composition The chemical characteristics of the fats used are shown in table II ** Except in the cases of butter and coconut oil, all fats fed were composed of fatty acids of similar chain length (predominantly C_{16} to C_{18}) To simplify the interpretation of such experiments, oils rich in trienes were purposely avoided (soybean, linseed oils)

The levels of serum-lipids produced by the feeding of each of these fats are set forth in table III Calculations were made of the absolute and percentage differences of these levels from the base line levels reached during the feeding of corn oil The results were related to a number of characteristics of natural fats—iodine number, linoleic-acid content, and biological activity in rats deficient in

¶ Chemical purifications of corn oil were generously accomplished by F F Drew & Co Dr V K Babayan

** We are greatly indebted to Dr Donald H Wheeler General Mills Inc to Dr Roy W Riemenschneider and Dr Waldo C Ault Eastern Utilisation Research Branch, U S Department of Agriculture and to Dr Fred Mattson Procter & Gamble Co, for numerous analyses and for their helpful advice on matters of fat technology essential fatty acids †† Absolute differences in lipid levels failed to correlate with any of these parameters However, a roughly linear relationship was obtained by relating percentage differences in cholesterol or phospholipid levels to the iodine values of the fed fats This analysis is shown in fig 7 The use of fats with iodine values below 90 produced levels of cholesterol significantly higher than the corn-oil base line (P<0 01) *in 23 of 26* tests However, fats with iodine values over 100 all produced equally low levels of cholesterol, suggesting a limit to the effect produced by the ingestion of unsaturated fats With the feeding of fats with iodine values below 90, the cholesterol content of the serum increased as the saturation of the dietary fat increased The plot of the phospholipid data showed the same type of correlation with a somewhat smaller dispersion of data In the case of the triglycerides there was no correlation with iodine value, all percentage differences falling within the ±25% limits of reproducibility noted above in the analysis of the corn-oil refeeding tests

Statistical analysis showed a significant correlation between P (the percentage decrease of total-cholesterol or phospholipid levels with a given dietary fat, relative to the corn-oil base-line) and the total iodine values of the fats fed An equally good correlation was found between P and the expression total saturated acids minus linoleic acid (S − L) Since our studies were performed with fats consisting almost exclusively of saturated (S), oleic (O), and linoleic (L) acids, it was simple to calculate that the iodine values of these fats are functions of any of the following expressions (S − L), (2S + O), or (2L + O) Thus I_T (total iodine value) = 90 − 0 9 (S − L), and (S − L) = 10 − 1 11 (I_T) With the natural fats available for feeding tests the variable (2S − L) also is practically a linear function of iodine value

Now, if our data can be correlated with iodine value they will *also be correlated with any of the* four alternative expressions To conclude that dietary oleic acid is neutral *or lacking in effect simply because the cholesterol data* can be correlated with some function of (S − L) or (2S − L) is no more correct than to imply that linoleic is unimportant because the data can be correlated with the expression (2 S + O) Correlations which utilise any of these modes of expression are no more meaningful *than an iodine*-value correlation

An analysis of variance was carried out to assess the relative importance of total unsaturation and the linoleic acid content of the various fats The linear regression of *P on total iodine* value of the dietary fats (I_T) was $P = -0\ 37\ I_T + 44$ The multiple regression of P on I_T and on linoleic acid, expressed in iodine-value equivalents ($I_L = L \times 1\ 8$) was $P = 0\ 14\ I_L - 0\ 49\ I_T + 47$ Comparison of residual variances showed that the multiple regression gave no better fit to the experimental data than the simple regression on total iodine value The simple regression of P on I_L gave a poorer fit than either of these (*P<0 05*)

It is noted that the butter and coconut oil data contribute heavily to the values of the regression coefficients Since it will be shown below that these fats may cause unusual effects on serum-cholesterol, perhaps due to their high *content of short-chain fatty acids*, it may be questioned whether it is permissible to include these *data in the mathematical analysis* Indeed, if they are excluded, the following regressions are calculated $P = -0\ 21\ I_L + 0\ 08\ I_T + 13$, $P = -0\ 16\ I_T + 24$, $P = -0\ 15\ I_L + 17$ No significant differences were found between the residual variances of these three regressions (F test) Comparison of these formulas with those given in the preceding paragraph suggests that the assembled data fall along *two* curves, a steep one in which the major factor is correlated with mean unsaturation, and a flat curve in which the content of short chain saturated fatty acids may be the dominant factor

It is a matter of great practical and theoretical interest to learn whether the observed effects of dietary fats on serum-lipids are caused by mean unsaturation, or by the content of a specific unsaturated acid such as linoleic acid, but it is clear that this issue cannot be resolved by tests *made* with commonly occurring natural fats The fatty-acid compositions of these fats are so constituted that there is great interdependence between I_T and L In fact, the coefficient of correlation (r) between I_T and L of all fats used in this study, excluding butter and coconut oil, is 0 88 ± 0 09 (P<0 01) When butter and coconut oil are included, r = *0 79 ± 0 12* (P<0 01), also a high degree of correlation If I_T and L are to be separately evaluated, it is obvious that tests must be

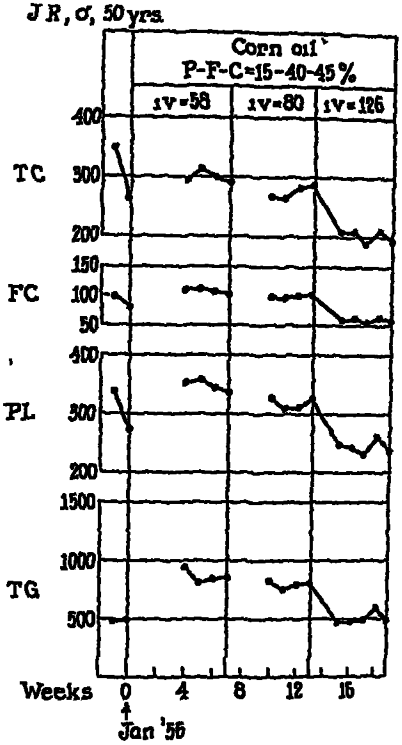

Fig 8—Effect in patient 20 of ingestion of corn oil hydrogenated to iodine values of 58 and 80, compared to unhydrogenated oil Levels of lipids significantly different (P<0 01), in three test periods

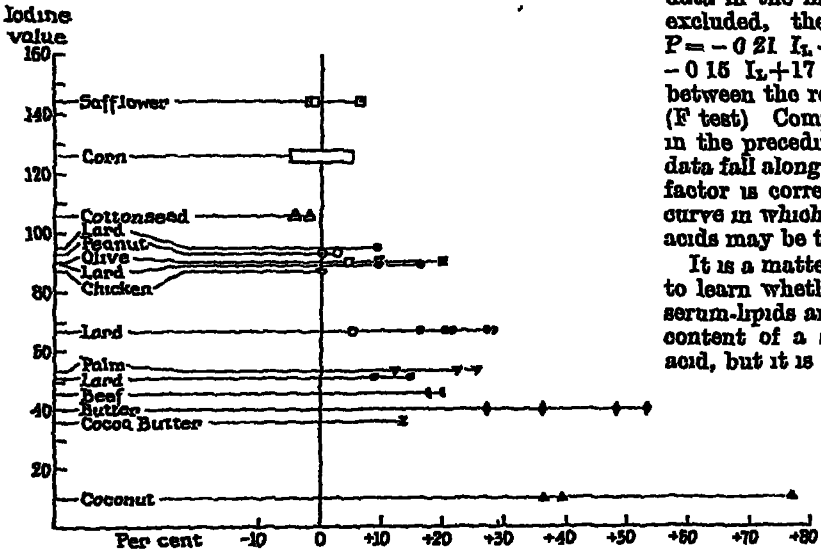

Fig 7—Relationship between iodine values of dietary fats and serum cholesterol levels, *expressed as percentage differences from base-lines established during ingestion of corn oil*

Iodine values of fats listed along vertical axis Open bar at I V 126 = estimated reproducibility of corn oil base line (fig 2) Open symbols represent results not significantly different from base line, solid symbols different at level of P<0 01, hatched symbols different at level of P<0 05 made with fats synthesised from pure acids The hypotheses suggested by our calculations can be critically evaluated only when I_T is held constant and L varies maximally, and vice versa It is idle at this time to carry the interpretations of the present data further than to state that the effect on serum-cholesterol and phospholipid levels is strongly correlated with the iodine value of dietary fat

---

†† A number of bio assays on fats used in these tests were generously performed by *Dr H J Thomasson, Unilever Research Laboratory*, Holland, by the methods described in *Internat Rev Vitamin Research*, 1953, 25, 62

Hydrogenated Fats

If unsaturation of fatty acids is responsible for the effects under study, the obliteration of double bonds by hydrogenation would be expected to mitigate the depressing action of these acids Complete hydrogenation of such long-chain fatty-acid oils as corn or cottonseed produces triglycerides composed of palmitic and stearic acids—fats with high melting-points which are poorly absorbed by the small intestine (Deuel 1954) To insure complete absorption of the fed fat the investigator is forced to use partially hydrogenated oils with melting-points below 50°C Partial hydrogenation is, however, not a simple process, and isomers are formed as well as simple hydrogen addition products (Sreenivasan and Brown 1956) The nutritional effects of partially hydrogenated oils have received extensive study (Deuel 1954), and in terms of growth, maturation, and reproduction such fats are equivalent to their natural precursors However, in terms of the parameters under study here the effects of these complicated mixtures are unknown Since *trans* acids do not replace *cis* acids in remedying essential-fatty-acid deficiency (Holman 1951, Privett et al 1955) it seems probable that the isomers found in partially hydrogenated fats are metabolised through different pathways

Three feeding tests were carried out with partially hydrogenated oils, fed in the basic formula as 40% of calories The most clear-cut response was shown by patient 20 (fig 8) in whom the feeding of corn oils hydrogenated to iodine values of 80 and 58 in a moderately selective process, produced progressively higher levels of cholesterol and phospholipids in the serum In patient 30, however, the ingestion of corn-oil, hydrogenated to an iodine value of 80, produced no higher levels of serum-lipids than the unhydrogenated oil In patient 18, serum-lipids were equally depressed on unhydrogenated corn and cottonseed oils, but the subsequent feeding of cottonseed oil, hydrogenated to an iodine value of 68 in a selective manner, produced a small but significant rise ($P<0{\cdot}01$) in cholesterol and phospholipid levels The compositions of these products are listed in table II, and the serum-lipid data in table III It is worth emphasising that in these 3 patients the entire fat intake consisted of fats hydrogenated more heavily than in the case of the margarines and shortenings commonly marketed in the United States (Sreenivasan and Brown 1956), yet in two of three cases serum-lipid levels were not so high as those found during ad-libitum feeding

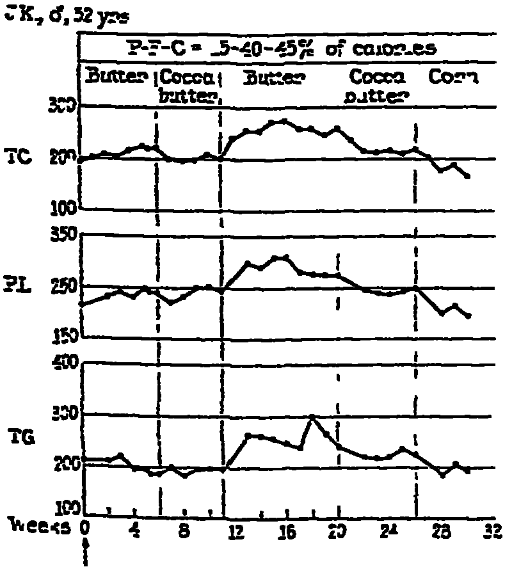

Fig 9—Feeding tests in patient 37 comparing butter and cocoa butter (experiment still in progress) These two fats have similar contents of saturated oleic, and linoleic acids (table II fig 11) but butter is rich in C_4-C_{14} fatty acids

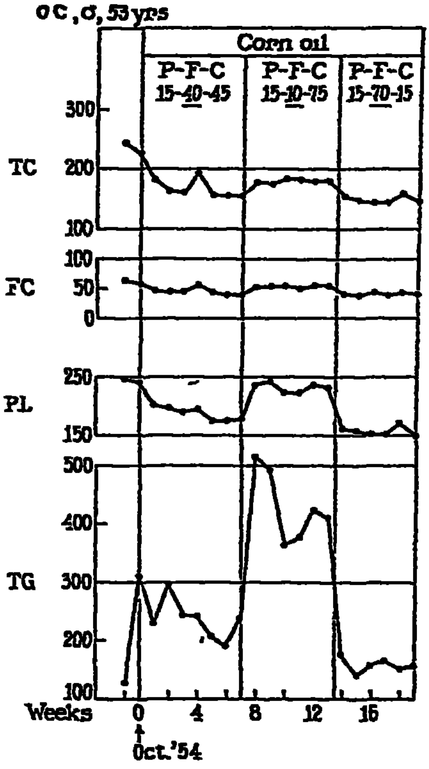

Fig 10—Effect on serum-lipids (patient 31) of varying the proportions of fat and carbohydrate calories reciprocally, keeping total calories, protein, and body-weight constant Major changes in triglycerides, smaller differences in phospholipids, and least striking effects on cholesterol Lowest serum lipids on highest intake of corn oil highest levels on lowest intake

Variations in Length of Fatty-acid Chains

The highest lipid levels encountered in our tests were produced by the feeding of butter and coconut oil (fig 7) While these oils were the most saturated of the dietary fats tested, it must be stressed that they were also the only fats which contained a high content of fatty acids with chain lengths less than C_{16} 25% of butter fatty acids have chain lengths of C_4 to C_{14}, while 60% of coconut-oil fatty acids have chain lengths of C_8 to C_{14} Thus, it is possible that the effectiveness of these fats in raising serum-lipid levels is due in part to the low content of unsaturated acids but also to the presence of short-chain acids

Experiments have been completed in patients 26 and 37 which were designed to test the importance of chain length as a variable In these tests butter was compared with cocoa-butter These fats are almost identical in iodine value and in percentage composition of saturated oleic, and linoleic acids (table II) However, the saturated acids of cocoa-butter are predominantly C_{16} and C_{18} acids, whereas 40% of the saturated acids of butter are C_4 to C_{14} acids Serum-cholesterol and phospholipid levels were significantly higher ($P<0{\cdot}01$) during butter-feeding periods in both patients (fig 9) The fats were apparently equally well absorbed, as evidenced by the constancy of body-weights over the many weeks of these tests when the formulas were isocalorically exchanged.

These results are interpreted as presumptive evidence that fatty acids of short and intermediate chain length cause higher lipid levels in the serum than do the long-chain saturated acids The short term feeding tests carried out by Beveridge et al (1957b) with fractions of butter prepared by molecular distillation seem to confirm this postulate Their highest cholesterol levels were produced by the fractions of butter containing the shortest and most saturated fatty acids However, in both laboratories' experiments the non-glyceride portions of the test fats also differed Therefore, final proof of this point awaits use of fats synthesised from pure fatty acids It seems clear that butter and coconut oil are not ideal prototypes of highly saturated fats for our experiments because of inhomogeneity in chain length of their fatty acids

Variations in Caloric Mixture

The response of patients to any given dietary fat is influenced not only by the chemical structure of the fat but also by the proportional contribution of fat to the total caloric intake These relationships are complex (fig 10) When only 10% of total calories was fed as corn oil, serum-lipid levels were significantly higher in all categories than when 40% or 70% of calories were derived from corn oil In fact, the lowest serum levels were attained on the highest fat intake Similar findings were made in three other patients This may be related to the presence in corn oil of factors which depress serum lipid levels, but clearly the proportions of non-fatty elements in the diet also may play an important modifying rôle It is important to note that the substitution of carbohydrate for fat calories produced major changes in the serum triglyceride levels, other lipids increasing less strikingly The regularity and dominance of this triglyceride response in all four patients contrasts with the lack of orderly change in this fraction in experiments where metabolic mixtures were held fixed while fats of varying fatty-acid composition were exchanged

Discussion

The results discussed above favour the hypothesis that serum lipids can be lowered by ingestion of highly

TABLE III—SERUM-LIPID DATA DURING STEADY STATES ON INGESTION OF VARIOUS DIETARY FATS

(Patient numbers refer to list in table I All food intake by method of oral formula feeding In all cases, just enough calories were fed to maintain constant body weight Protein calories were uniformly 15% of the total, fat and carbohydrate calories varying reciprocally as designated in third column Means, ±1 standard deviation, are shown in all cases)

unsaturated oils. The salient points supporting this contention are:

(1) Feeding-tests with dietary fats rectified in various ways suggest that the major influence on serum-lipid levels is exerted by the glycerides, not the non-saponifiable fraction.

(2) The lowest serum-lipid levels were seen when corn oil, safflower-seed oil, or cottonseed oil constituted the sole dietary fats. Higher levels were found with all other fats tested. The differences in these levels are directly related to the degree of saturation of the glyceride fatty acids as measured by the iodine value of the fat.

(3) Use of hydrogenated corn and cottonseed oils as sole dietary fats resulted in higher serum lipid levels than when the corresponding unhydrogenated oils were fed.

The experiments of Kinsell and Michaels (1955), Bronte Stewart et al. (1956), and Beveridge et al. (1956) produced qualitative data which accord with this hypothesis. It is noteworthy that, despite major differences in experimental design, the investigations of four groups led to the same tentative conclusions. Thus, the same type of response in serum-cholesterol levels was obtained when unsaturated fats were substituted for saturated fats in the diets of young normocholesteræmic medical students, vitamin- and protein-deficient normocholesteræmic Bantus, and Americans with and without high serum-cholesterol levels and arteriosclerotic heart-disease. Three groups kept caloric intakes and proportions of foodstuffs in the diet unchanged in comparative feeding periods; the South African experiments yielded qualitatively similar results even though these controls were lacking.

In our investigations the number of patients studied was limited by the long duration of the feeding tests, but

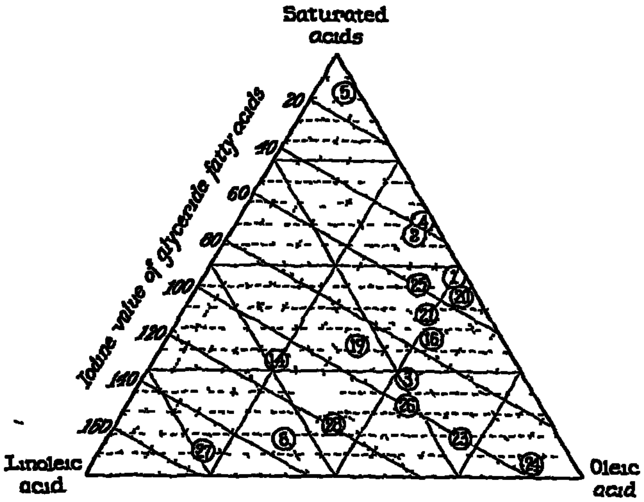

Fig 11—Triangular plot of fatty acid compositions of fats used in present studies

Corners represent 100% of linoleic, oleic, and total saturated acids, respectively, while sides represent 0% of the component in the opposite corner *Fatty acid mixtures having the same* iodine value are joined in a series of parallel lines, iodine values of the glycerides composed of these acids are about 5% *lower than those shown* Numbers in circles refer to fats listed in table II

our design allowed a quantitative comparison of the effects of various dietary fats Minimum feeding-periods of 5 weeks for each diet made possible the accumulation of serum-lipid data after steady states were reached, and minimum study-periods of 4 months provided data from several steady states in each patient During these periods all the major lipid classes in serum were measured at weekly intervals, affording for the first time a total analysis of the serum lipid picture The base line data obtained during the feeding of the corn-oil formula served as a common denominator when it was desired to compare quantitatively the varying responses of *patients to other dietary fats* The *use of this common* denominator was validated by the finding that patients' lipid levels returned to the same point whenever they ingested this oil It is probable that any dietary fat may serve the same purpose, for in a limited number of refeeding trials *other fats* and *oils* also have evoked serum-lipid responses which were reproducibly characteristic of the fat fed

This quantitative technique has provided evidence which strongly suggests that the effect of dietary fats on serum-cholesterol and phospholipid levels is a function of their iodine value *It cannot be stated at present if* this effect is more dependent on mean unsaturation of the fed fat than on its content of a specific unsaturated acid, such as linoleic, this issue remains to be clarified *in future experiments* Whether linseed oil (rich in triethenoid C_{18} acids) or fish oils (rich in tetraene, pentaene and hexaene acids of C_{20} to C_{22} chain length) will produce effects as great as, or greater than, the oils so far tested has not been investigated under our experimental conditions *For* the present it is profitable to analyse the response obtained in terms of the three major constituents of the fats used, namely, the total saturated fatty acids, the monoethenoid acid, and the diethenoid acids All the fats discussed in this report were composed of only these three components, if for the moment the nonsaponifiable material in these fats is disregarded There fore, it is possible to compare their composition graphically in a triangular diagram Fig *11 presents the data of* table II in this form This manner of representation has proved exceedingly useful to us in planning critical experiments Thus, to define the effect of iodine number while holding linoleic-acid content fixed, the investigator selects fats which lie on the same linoleic acid line (e g, olive oil and palm oil), but which vary maximally in iodine number (92 and 57, respectively) because of reciprocal variations in saturated and oleic acids Experiments designed to weigh the relative effects of the three postulated variables will be reported later

It has been of interest to us that all reported analyses of natural fats made up only of these three groups of acids spread across the triangle in an arc from linoleic toward oleic and then upward to the saturated corner Thus, a large portion of the triangle is unoccupied, representing an absence in Nature of fats rich in linoleic and saturated acids but poor in oleic acid The oleo margarines produced in the 1930s before the development of partial-hydrogenation procedures were blended mixtures of unhydrogenated with completely hydrogenated oils Such blended fats would lie in the portion of the triangle not occupied by any of the natural fats Materials of this type, which may become of interest once again as margarines and *shortenings, are currently being evaluated* in our programme

Over each locus on the triangular plot a vertical bar can be erected, the height of which is proportional to the degree of response of a serum-lipid to ingestion of that *particular fat* In *fig 12, serum cholesterol responses* are related to the compositions of the various fats and oils shown in fig 11 The shortest bars depict the lowest cholesterol levels, the longest bars the highest levels Each bar denotes a single feeding-test The average heights of the bars at each locus suggest a second surface with a contour which sweeps from the lower left corner upward *to the right* and then *still higher to the* upper corner It will be of interest to define the shape of this contour more exactly

Our present line of *investigation* has aimed at defining the specific dietary factors which cause the rises and falls in serum-lipid levels demonstrated above An understanding of the mechanisms involved in these changes clearly demands a thorough preliminary exploration of *food factors* *If it is finally established that the* phenomena under study are in fact due to the nature of the fed

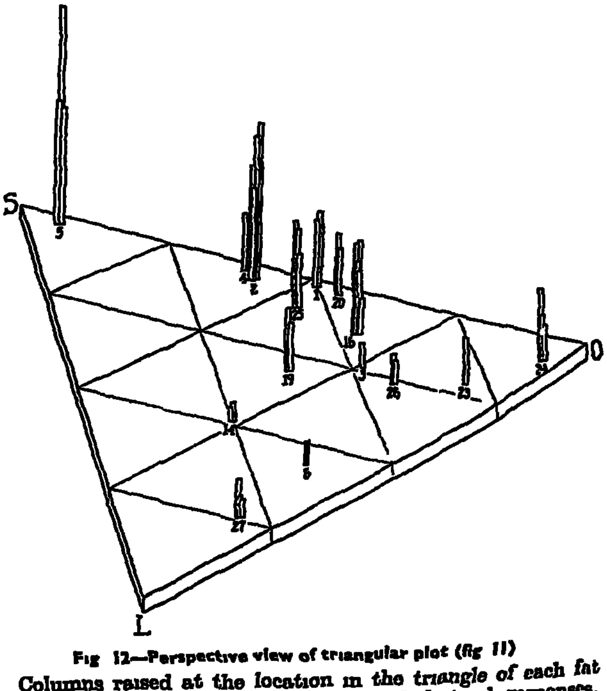

Fig 12—Perspective view of triangular plot (fig 11)

Columns raised at the location in the *triangle of each fat* are proportional in height to serum cholesterol responses, expressed as percentage differences from corn oil base lines Each column represents an individual *feeding experiment* A second contour surface is suggested fatty acids and not to trace components in the oils so far tested, it may be profitable at this point to enumerate some of the questions which will require answers If unsaturated acids cause lower lipid levels, is this due simply to the number of double bonds per unit weight of *methylene groups, as our data suggest at present*, or is the effect caused by certain unsaturated fatty acids and not by others ? Do the monoenes have half the potency of the dienes ? Are trienes more effective than dienes ? Are conjugated double bonds as effective as non conjugated ? Do saturated acids, per se, cause higher serum lipid levels, and if so, do all chain lengths have the same effect ? What is the effect of ingestion of the fatty acid isomers produced by hydrogenation processes ?

Assuming that the net effect of ingestion of a mixture of various fatty acids can be defined at one caloric level, what changes will be produced when the proportions of fat, carbohydrate, and protein are varied ? It was stressed that this manipulation of dietary intakes had its major effect on the serum triglycerides, other serum-lipids varying in parallel but to a smaller degree There have been many proponents of the low-fat diet, but few have measured the triglyceride response to this metabolic mixture Hatch et al (1955) studied the serum-lipid spectrum in forty-four patients subjected to a strict rice diet They noted that in one-fifth of these patients visible lipæmia developed with a marked rise in triglycerides, in addition, ultracentrifugal patterns of the lipoproteins showed rising concentrations of S_f20–100 species in all eleven patients so tested Comparable trends were observed in our four patients who were given varying ratios of carbohydrate and fat calories In the one patient so tested there was a dramatic rise in alpha$_2$-lipoproteins and in $S_f > 20$ species on low-fat regimens, and a reversion to normal on the 70% fat intake We recognise that high levels of cholesterol and phospholipids on ad libitum diets may be reduced on a low-fat regimen, at least temporarily, but in our experience a high intake of unsaturated fat leads to even more striking decreases in these serum components and in addition avoids increases in triglycerides

Our readiness to accept the unsaturation hypothesis as firmly proven has been tempered by the realisation that none of the experiments performed here or elsewhere has ruled out the possibility that the factors sought may lie in the non-glyceride portion of the fed fats In fact, in a recent abstract Beveridge et al (1957a) concluded that the "plasma cholesterol depressant effect of corn oil depends to a large extent upon its sterol content" Our tests with molecularly distilled corn oils and with reconstituted corn oil glycerides containing small amounts of non saponifiable material suggest that, if a trace factor is involved, it must be active in extremely low concentration By chemical processes on a pilot plant scale it was possible to reduce sixfold the content of non saponifiable material in corn oil The same order of magnitude of change in intake of non-saponifiable material was also achieved by reducing the intake of whole corn oil from 70% to 10% of calories In the latter experiment (fig 10) the depressing effect of corn oil on serum-lipid was lost, yet after a sixfold decrease in non saponifiable material by chemical treatment, the depressing effect was not lost (fig 6) Clearly, the resolution of this issue awaits completion of feeding tests with glycerides synthesised from pure fatty acids The great cost of producing sufficient amounts of pure acids has delayed the accomplishment of these critical experiments

It is often asked whether patients are clinically improved when their serum lipids are held continuously at a lower level by the regimens discussed in this report On the whole, our patients have shown considerable subjective improvement while under our care But we believe that this is primarily due to daily medical attention, to prolonged restriction of physical activity under pleasant hospital circumstances, and to our continual efforts to educate them about their disease Patients who have gained the most reassurance have unquestionably benefited the most Because so many non-specific factors have profoundly affected our patients' clinical status, it is impossible at this time to attribute to our dietary management any specific therapeutic merit In fact, we consider hazardous any short-term evaluation of a therapeutic regimen in patients with coronary-artery disease Until it becomes possible to assess the progress of the atheromatous process during life, it will be exceedingly difficult to determine whether a therapeutic measure is effective It has been gratifying to observe the disappearance of skin xanthomata in patients with hyperlipæmia or hypercholesteræmia, but we have seen no changes in tendon xanthomata despite marked decreases in serum-cholesterol levels for as long as 2 years It is an open question whether atheromata respond to this regimen as do skin xanthomata, or fail to be appreciably influenced like tendon xanthomata

It is our present conclusion that recommendations for radical changes in food habits, even by those populations most seriously threatened by atherosclerosis, should await a clearer definition of the specific food factors which control serum-lipid levels It is entirely possible that an understanding of the mechanisms evoked by these factors will lead to practical measures for control of serum-lipid concentrations Only then can large-scale epidemiological experiments be planned to determine whether the incidence of atherosclerosis and its complications in the human species will be affected by decreasing the levels of lipids in the serum

These studies were supported in part by the Williams Waterman Fund, the Nutrition Foundation, and the U S Public Health Service (National Heart Institute, H 2539)

The names of many helpful colleagues have been mentioned above In addition, we wish to acknowledge our gratitude to Dr W Henry Sebrell, jun, for his interest and advice, and to Dr R A Reiners (Corn Products Refining Co) and Dr H J Anderson (Cudahy Packing Co) for generous assistance in procurement of special fats

PRINCESS MARY MATERNITY HOSPITAL,
NEWCASTLE UPON TYNE

From the Princess Mary Maternity Hospital, and the Departments of Child Health and Pathology, King's College, University of Durham

THE death of a newborn infant after cæsarean section is particularly disturbing because the operation is usually performed to save the infant's life. The decision to use this method of delivery has been made more difficult in recent years by the recurring suggestion that cæsarean section itself carries special and serious hazards for the infant.

Potter (1943) and Potter and Rosenbaum (1943) described a fatal syndrome preceded by mounting respiratory distress which was regarded as due to cæsarean section. This has been called the "cæsarean section syndrome" and has been regarded as a direct effect of the operation (Bloxsom 1942, Williams 1950, Simpson and Geppert 1951, Smith 1953).

Our attention was first drawn to this question in 1951, when, by agreement with our obstetric colleagues, pædiatric care in this hospital was extended to include resuscitation of the newborn. This required attendance of a pædiatrician at every abnormal delivery, including cæsarean section. We were anxious to establish whether the operation carried a special risk for the baby, and, if it did, to discover whether any modifications in our method of resuscitation were necessary.

At first sight the published figures for neonatal deaths after cæsarean section supported the view that it carried a high risk for the baby.

Marshall and Cox (1949) reported a neonatal death rate of 5·2% in a study combining the results of many centres. It was clear, however, that their material included many serious obstetric emergencies which exposed the baby to risks quite apart from those of cæsarean section.

Similarly, reports describing the "cæsarean section syndrome" included examples in which placenta prævia and rupture of the uterus were indications for the section (Potter and Rosenbaum 1943, Williams 1950).

Scope of Inquiry

As we considered these reports, it seemed clear that an assessment of the effect of cæsarean section on the baby could be made only in cases free from complications which were injurious in themselves. The maternal and neonatal case records of all cæsarean sections performed in this hospital in 1946–50 were therefore examined, but consideration was confined to those in which the reason for the cæsarean section was disproportion or uncomplicated pre-eclampsia before the onset of labour.

In this study (Strang 1953) all the deaths except one could be adequately explained on the grounds of malformation, prematurity, or hæmolytic disease. The exception, that of a mature baby, was due to a sudden massive pulmonary hæmorrhage on the fourth post-operative day. As this was the only unexplained death, we concluded that we had no convincing evidence that cæsarean section harmed the mature baby.

The numbers of premature babies available for study were too small to measure the effects in their case. We were encouraged to continue our observations, however, by the report of Hamilton et al. (1949), which suggested that cæsarean section is more favourable than surgical induction and vaginal delivery for the small premature babies of toxæmic mothers.

In the following five years (1951–55) we continued our study of babies delivered by cæsarean section. During this time several reports have appeared which include data supporting the view that elective cæsarean section does not carry a special risk for the baby.

Landsman (1951), after allowing for congenital malformations, had a neonatal mortality of 0·4% in 534 cæsarean sections for disproportion, and he concluded that the high overall mortality of cæsarean section was related to the indication rather than to the operation, and that cæsarean section for disproportion is no greater risk to the infant than spontaneous vertex delivery.

Williams and Hollenbeck (1952) reported, in 148 repeat cæsarean sections, 5 neonatal deaths, of which 2 were due to hæmolytic disease of the newborn and 1 to congenital malformation.

Carey (1955) had only 2 deaths in 679 "elective" cæsarean sections which could not be explained on grounds of blood disorder, congenital malformation, or prematurity.

In 321 "elective" cæsarean sections Posner et al. (1954) reported only 2 deaths, 1 from congenital heart disease and 1 from pneumonia.

A division of opinion on this question persists. Thus Montgomery et al. (1956), introducing important work on the blood oxygen saturation after vaginal and cæsarean delivery, said: "It is a generally accepted observation in obstetric and pædiatric circles that babies born by Caesarean Section do not do as well as those born by vaginal delivery." Because of this divided opinion we have decided to review our experience and to present our findings for the whole ten years *1946–55*. We have done this from our initial premisses: (1) that an assessment of the effects of cæsarean section on the baby is possible only in absence of *other obvious risks*; and (2) that mature and premature babies require separate consideration. During the second five years we made personal observations on the immediate newborn period, noting particularly the time taken to establish regular respiration.

Methods

The maternal and neonatal records for all cæsarean sections in the Princess Mary Maternity Hospital for 1946–55 were examined. *Stillbirths were excluded* because the issue concerned the influence of cæsarean section on the baby after delivery. The remaining records were divided into "elective" and "not elective".

Elective.—Cases in which a decision was made during the antenatal period to perform a cæsarean section and in which it was carried out before or within a few hours of *the onset* of labour. These included cases of disproportion from any cause and some cases of pre-eclampsia terminated by cæsarean section.

Not elective.—All other cæsarean sections, including emergencies of all kinds and cæsarean section terminating trial of labour. Included also were cases of hæmolytic disease of the newborn and maternal complications such as diabetes mellitus, heart disease, ante-partum hæmorrhage, and eclampsia.

Pre-eclampsia was included in the elective group on the basis of Drillien's (1947) *finding that*, in comparable weight groups, the infants of toxæmic mothers have survival-rates as good as those of infants of mothers without toxæmia. *In 27 of 36 premature cæsarean sections* the indication was the termination of severe pre-eclampsia. In some mature cases a mild pre-eclampsia coexisted but was not itself the indication for cæsarean section.

The fate of the babies in these two groups was determined by examining their neonatal records, and a note was made of any respiratory illness in the survivors and of any resuscitation required. In the deaths, the necropsy records, and where possible the histological sections, were examined.

Results

Mortality

Table I sets out the mortality after elective cæsarean section as defined above The corrected mortality after removal of deaths due to congenital malformation is also shown Of 251 mature babies 5 died The details of these are

TABLE I—NEONATAL MORTALITY IN ELECTIVE CÆSAREAN SECTION

—	Total	Deaths	"Corrected" deaths
Mature	251	5 (2 0%)	2 (0 8%)
Premature	36	9 (25%)	7 (19%)

Case 1 —Birth weight 6 lb 2 oz Infant became cyanosed at twenty four hours and died at forty-two hours Necropsy revealed dilated bladder with congenital atresia of urethra Lungs showed pulmonary hyaline membranes [1946 B 2162]

Case 2 —Birth-weight 5 lb 11 oz. Intestinal obstruction, operation at seventy-eight hours Obstruction due to extensive adhesions could not be relieved. [1947 B 1283]

Case 3 —Birth-weight 6 lb 2 oz This infant was observed with particular care and was quite normal until eighty-five hours. She then suddenly became cyanosed, with lung crepitations and a gush of blood from the mouth, and died at sixty-three hours. Necropsy revealed massive pulmonary hæmorrhage and pulmonary hyaline membranes [1948 B 1482]

Case 4 —Birth-weight 6 lb 8 oz. Died at forty minutes Necropsy revealed congenital laryngeal stenosis admitting only a fine probe [1947 B 1712]

Case 5 —Birth-weight 5 lb 15 oz Apparently normal until fifty five hours, when baby became suddenly ill, with gush of blood from mouth, and died at sixty-three hours Necropsy revealed massive pulmonary hæmorrhage, no hyaline membranes [1953. B 450]

The 3 deaths due to congenital malformations cannot be put down to cæsarean section The 2 deaths in mature babies with massive pulmonary hæmorrhage are a strange and unexplained finding but we have no good reason for attributing them to cæsarean section They are quite different from the "cæsarean-section syndrome" which has been described. Nevertheless we cannot deny that cæsarean section might have played a part in these deaths If massive pulmonary hæmorrhage is to be regarded as a possible complication of elective cæsarean section it has an incidence of 0 8% in this material

Premature Babies

The results for premature babies (table I) are more difficult to assess The numbers are too small to permit a statistical comparison with normal vaginal deliveries in comparable weight-groups It can be shown however, that the mortality after "elective" cæsarean section is of the same order as for the whole group of premature babies The results for all premature deliveries in this hospital for 1946–55 are given by weight-groups in table II, and in table III the results for cæsarean sections are compared with "expected" figures for these numbers on the basis of the figures in table II The total mortalities compared in this way appear to be similar

Necropsy was performed in 8 out of 9 premature deaths and the causes of death were severe congenital malformations, 2, massive pulmonary hæmorrhage 2, pulmonary hyaline membranes 3, and cerebral œdema only 1 In these deaths there was no unusual preponderance of pulmonary hyaline membranes, which Smith (1953) has regarded as the basis of the "cæsarean-section syndrome."

TABLE II—MORTALITY OF PREMATURE BABIES AFTER ALL FORMS OF DELIVERY (1946–55)

Birth weight	Total	Deaths
<2 lb 9 oz	98	91 (93%)
2 lb 9 oz.–3 lb 8 oz.	224	104 (46%)
3 lb 9 oz.–4 lb 8 oz	485	68 (14%)
4 lb 9 oz.–5 lb 8 oz.	1236	79 (6%)
Total	2043	342 (17%)

Morbidity in Surviving Babies Delivered by Cæsarean Section

During the ten-year period records were kept of every type of illness in all babies, and for 1951–55 records were also available of the time taken to establish regular respiration 1 mature and 2 premature babies developed an episode of respiratory distress requiring oxygen and lasting twelve to twenty-four hours All recovered completely 1 mature baby developed a mild irritability requiring sedation but also recovered satisfactorily There was no other illness in survivors In 113 babies the time taken to establish regular respiration (one to thirteen minutes mean, five minutes) was longer than after vaginal delivery This delay was probably due to the maternal anæsthetic and no harm was noted

Resuscitation of Newborn after Cæsarean Section

Some workers who have accepted the idea of a "cæsarean-section syndrome" have advanced explanations and advocated preventive measures based on these theories Potter and Rosenbaum (1943) associated the syndrome with the necropsy finding of excess cerebrospinal fluid in the subarachnoid space, and Bloxsom (1942 1953) recommended that labour should be allowed to start and progress for a few hours before any cæsarean section, in order to subject the fœtal head to compression Landau et al (1950) have suggested that the cæsarean baby is deprived of a normal transfusion from the placenta during labour and that the "cæsarean section syndrome" is due to partial exsanguination and consequent shock These workers recommend that after delivery the placenta, still attached to the baby, should be suspended until all its blood has drained into the baby's circulation Smith (1953) equates the "cæsarean-section syndrome" with pulmonary hyaline membranes and regards the increased liability to this as due to the inhalation of liquor, which has been shown to be present in excess in the stomachs of cæsarean babies (Gellis et al. 1949)

TABLE III—MORTALITY OF PREMATURE BABIES AFTER ELECTIVE CÆSAREAN SECTION COMPARED WITH "EXPECTED" MORTALITY

Birth weight	Total	Deaths	"Expected" deaths
<2 lb 9 oz	2	2	2
2 lb 9 oz –3 lb 8 oz	7	4	3
3 lb 9 oz.–4 lb 8 oz	12	1	2
4 lb 9 oz –5 lb 8 oz.	15	2	1
Total	36	9	8

Though we cannot accept the idea of a "cæsarean-section syndrome" we believe that the cæsarean baby requires special care after delivery The baby is usually anæsthetised and may be unable to cough clear any obstructing mucus, and large volumes of liquor may drain from its stomach Recent studies suggest that the full oxygenation of the blood may be delayed (Montgomery et al 1956) and that the blood-pressure may be lower initially than after vaginal delivery (Holland and Young 1956)

Our practice is as follows The obstetrician allows the cord to empty before it is divided The baby is then handed to the pediatrician, who normally performs a rapid laryngoscopy and removes by suction any obstructing mucus and then places the baby head-down in oxygen, the liquor being allowed to drain from the mouth If the onset of respiration is delayed beyond five minutes, the stomach is emptied by suction, and intragastric oxygen is given

In 1951–55 records of resuscitation were available for 91 mature and 22 premature babies delivered by elective cæsarean section Thick mucus requiring aspiration was found in 7 mature and 1 premature infants Intragastric oxygen was given to 1 mature and 2 premature infants As stated above, there was 1 unexplained death in mature babies in the five years before our resuscitation routine was started, and 1 similar death since it has been practised It is evident that we cannot expect to see any obvious benefits from these measures in terms of reduced mortality, but it is also clear that it would be unwise to omit them

Discussion

Because cæsarean section is so often the method of delivery when a serious obstetric complication is present, more babies die after it than after normal delivery The allegation that the operation introduces a further substantial hazard has not in our view been proved We believe that a misconception has arisen because attention has been focused on the whole group of cæsarean section, whereas a true assessment of the effects of the operation is possible only in cases free from all other risks

Our results for mature babies leave little doubt that the risk for them in elective cæsarean delivery is small In our material unexplained pulmonary hæmorrhage had an incidence of 0 8%, and we think it unlikely that the risk is higher than this Similar unexpected death after perfectly normal vaginal delivery is by no means unknown in our experience Because of our small numbers a definite statement on the delivery of premature babies by elective cæsarean section cannot be made, and it is arguable that larger numbers might demonstrate a definite hazard However, the evidence of Hamilton et al (1949) is against this

The amount of respiratory illness observed in survivors was *trifling*—only 1 mature and 2 premature babies were involved Although the onset of regular respiration was delayed, there is no evidence that this was harmful or due to anything other than the effects of the maternal anæsthetic We believe, however, that the anæsthetised state of the baby is a sufficient reason for practising a simple routine of resuscitation designed to maintain a clear airway

Although, in assessing the effect of the operation on the baby, we have regarded it as essential to consider only cæsarean sections free from complications, in these cases there is usually no alternative method of delivery The choice of method usually has to be decided in situations complicated by adverse factors If we accept that cæsarean *section* carries very little risk in the simple cases which we have termed "elective," we might reasonably argue that it does not add to the hazards of the complex cases in which a decision is really important The choice often involves the delivery of a premature baby, and we therefore hope that it will be possible in future to build up a larger experience of the behaviour of premature babies after elective cæsarean section

Summary

A "cæsarean section syndrome" has previously been described in which the death of the infant with respiratory distress has been attributed to the operation

The maternal and neonatal records were examined of 287 cases (251 mature infants and 36 premature) in which there was no complication of pregnancy or labour other than disproportion or pre eclampsia

In the 251 mature infants there were 5 neonatal deaths —3 from congenital malformations and 2 from massive pulmonary hæmorrhage

The results for 36 premature infants were of the same order as for the whole group of premature babies in this hospital, and an unduly high incidence of hyaline membranes was not detected

Only 3 of the surviving infants had an episode of respiratory distress

It is suggested that, though the infant who has been delivered by cæsarean section will benefit from close attention in the immediate neonatal period, cæsarean section does not carry an appreciable extra risk for the baby

We wish to thank Prof Donald Court, Prof H Harvey Evers, and Dr G A Neligan for their helpful criticism

THE importance of the chronic or recurrent wheezing which occurs in association with several pulmonary disorders lies in the fact that it is potentially reversible Whereas wheezing can almost always be controlled when the patient is in hospital, its treatment in ambulant patients is considerably less satisfactory and considerably more difficult to assess We have tried to assess the effects of five drugs, four of which are *known* to have a bronchodilator effect under controlled conditions, when each was given for a week in commonly used dosages under conditions approximating to those of ordinary outpatient practice In a pilot trial no objective benefit was demonstrable with oral ephedrine (Hume and Gandevia 1957a)

Plan of Investigation

The four bronchodilator drugs tested, with their dosages, were as follows

(1) 'Theodrox' *one* tablet three times daily, each tablet containing aminophylline gr 3 and dried aluminium hydroxide gr 4

(2) Aminophylline suppositories *one* three times daily, each containing aminophylline gr 4

(3) Choline theophyllinate one tablet (200 mg) three times a day

(4) Isoprenaline one tablet (10 mg) three times a day *sublingually*, increasing to two tablets three times a day or until side effects became unpleasant

---

† *Present address* King Edward VII Sanatorium Midhurst, Sussex

Aminophylline, choline theophyllinate, and isoprenaline have all been shown, by us and other investigators, to have an unequivocal bronchodilator action in short-term experiments. The theophylline content of aminophylline is 75–82% and of choline theophyllinate 64·4%.

For purposes of comparison phenobarbitone gr. $^1/_2$ twice daily, increasing to three times a day after five days, and a placebo composed of calcium carbonate and a trace of quinine sulphate one tablet three times a day were also included in the trial. In several patients we were unable to demonstrate a bronchodilator effect of phenobarbitone after a single dose of gr. 1. The dosages of all the drugs were the largest we were prepared to use in an experiment on volunteers, in whom it was desirable to keep side effects to a minimum.

The design of the experiment took the form of latin squares, whereby all the drugs were in use throughout the trial, each patient taking a different drug each week. There were six groups of 3 patients, each group being allotted a different drug weekly according to a predetermined plan. A design of this type ensures that the overall comparisons between drugs are not affected by temporal differences in, for example, climatic conditions or by the order in which the drugs are taken. The default of several patients made formal statistical analysis of this design impracticable but did not detract greatly from its basic advantages. The data were finally analysed as a simple randomised block design.

18 patients were selected from among 40 volunteer patients attending the physiotherapy department of the Brompton Hospital. The remaining 22 patients were excluded because they did not show at least a 10% improvement in either vital capacity or in the volume of air expired in the first second of a forced expiration following the inhalation of a 1% isoprenaline aerosol. The plan of the experiment and the necessity for full coöperation over the whole six weeks were explained to all the patients individually. We have every reason to believe that they adhered faithfully to instructions, probably more so than any unselected series of out-patients.

At the time of the investigation, in the summer of 1956, all the selected patients had wheezing as a prominent symptom and rhonchi as a physical sign. All complained of cough with some sputum, which had been yellow at some time in all but 1 patient. The diagnoses recorded in the case-notes, made on clinical and radiological grounds, were as follows: asthma (2), chronic bronchitis (2), asthma and bronchitis or asthmatic bronchitis (6), bronchitis and emphysema (8). 6 of the patients were women. The ages ranged from 25 to 69, and 15 patients were aged more than 40. Their clinical status is reflected in the proportion of the *forced vital capacity* (F.V.C.) which is expelled in the first second; this is called the *forced expiratory volume at one second* (F.E.V.$_{1.0}$). The word forced indicates that the vital capacity breath is expelled as rapidly as possible. Normally the F.E.V. is 75–85% of the F.V.C.; in our series of patients this proportion averaged 51% (37–68%).

All but 3 of the patients completed the trial. These 3 may be regarded as not having entered it, for they had to be withdrawn within the first few days for reasons unrelated to the experiment. Of the remaining 15 patients 2 stayed away on one occasion each.

1 woman was confined to bed by a severe exacerbation of her asthma (the only patient to suffer this in the six weeks of the trial) while taking isoprenaline tablets (this compound was subsequently found to have given no definite benefit in the remaining patients), and 1 man, taking choline theophyllinate missed the final assessment because of a miscalculation of his holiday dates. Both these patients' opinions (see below) of the two drugs they were taking at these times are available.

With the coöperation of the physicians and general practitioners concerned all other regular bronchodilator therapy was discontinued, the proviso being made that an exacerbation was to be treated as the general practitioner thought fit. The patients were allowed to continue with any sprays or tablets which they were taking only intermittently "when necessary," but each week they were asked to take into consideration the amounts which they had required when making their assessments of the value of the current trial drug.

The male and female patients were separately allocated at random into the required six groups, one for each drug. At each weekly visit each group obtained a supply of the drug to be taken for the following week. Until after the results had been collated and a preliminary analysis completed, the drugs were known to us only by their allotted code names.

Progress was assessed weekly in two complementary ways:

(1) The patient's opinion of each drug, based on his own assessment of his clinical condition over the appropriate week, was obtained by means of a questionnaire filled in at each visit. Several preliminary questions relating to the dosage of the trial drug taken, the time of the last dose, side effects, and the amount of other intermittent medication taken ensured that the patient gave careful thought to his condition before expressing his opinions. He was then required to select the most appropriate of four statements, corresponding to "worse,"[‡] "the same," "slightly better," and "much better," relative to his usual state, for which a point score of – 1, 0, 1, and 2 was made accordingly.

(2) The second method of assessment was objective—the measurement of the volume of air expired in the first second of a forced maximal expiration after a full inspiration (F.E.V.$_{1.0}$). This test is quicker and less distressing than the maximal breathing capacity test. The two are comparable in their sensitivity to the influence of a bronchodilator drug, both being more sensitive than the forced vital capacity (Hume and Gandevia 1957a). It is also more sensitive than the two-second volume (unpublished data confirmed for the present series of patients by analysis of the effects of inhaled isoprenaline), and it is generally regarded as a more repeatable measure than the forced vital capacity. The F.E.V.$_{1.0}$ was measured on a spirogram obtained from a spirometer of the type described by Bernstein et al. (1952), a peripheral drum speed of 16 mm. per second being used. The highest value derived from three satisfactory tracings was used; no correction for either temperature or pressure was applied. The tests were made with the patient seated and were supervised throughout by the same observer. The patients attended at the same time on the same afternoon of each week, the tests being made at the same time (between one and three hours) after the last dose of the drug under trial. A learning effect in the performance of the tests was not apparent, but the results of tests made in the preliminary examination and on the day of issue of the first series of drugs provided useful practice.

Each week half of the patients, always including the patients currently receiving the placebo, inhaled a mist of 1% isoprenaline administered with a Bright inhaler for one and a half minutes, after which the F.E.V.$_{1.0}$ was again measured. The chief purpose of this procedure was to provide a familiar standard—i.e., response to a commonly used aerosol—for comparison with the results obtained for the several trial compounds.

Results

We believe that the patients carried out the prescribed régime for each drug very well. No serious side-effects were observed. Only 1 patient (taking isoprenaline tablets) had a disabling exacerbation of asthma during the trial. The data for the objective assessment (F.E.V.$_{1.0}$), which it is convenient to consider first, were

---

[‡] The statement "This treatment has not suited me at all" was used in preference to "This treatment has made me worse" to avoid the implication that bronchoconstricting agents had been deliberately included. Patients who were worse knew that this was the appropriate statement to mark as their opinion.

TABLE I—F E V$_{1 0}$ AT END OF TREATMENT WITH PLACEBO AND EACH DRUG AND PERCENTAGE CHANGE

Drug	Mean F E V$_{1 0}$ of 13 patients (c cm)	Mean percentage change on individual placebo values (standard deviation)
Placebo	1170	
Aminophylline suppositories	1350	+20 4 (35 8)
Choline theophyllinate	1310	+15 0 (15 7)
Theodrox	1220	+ 7 1 (8 8)
Sublingual isoprenaline	1210	+ 7 5 (26 7)
Phenobarbitone	1200	+ 4 5 (14 9)
Placebo plus isoprenaline aerosol	1180	+27 8 (13 1)

The results for the placebo plus isoprenaline aerosol are shown for comparison

analysed only for the 13 patients who were regularly assessed

The mean weekly F E V$_{1 0}$ of the 13 patients was the same throughout the experimental period, ranging only from 1210 to 1290 c cm This gratifying lack of variability with time in the series as a whole adds significance to the analysis in terms of the influence of the drugs

The mean F E V$_{1 0}$ after a week's treatment with the placebo and each of the drugs is set out in table I, together with the percentage change calculated from the values obtained for the placebo in each patient The percentage increase produced by administration of isoprenaline aerosol, in addition to the placebo, is also shown The table affords an easily appreciated comparison of the drugs, but detailed statistical examination was done after logarithmic transformation of the data to reduce the range of variation between patients or, more strictly, to validate certain assumptions implicit in making an analysis of variance

TABLE II—RESULTS OF ANALYSIS OF VARIANCE ON LOG F E V$_{1 0}$ VALUES FOR 13 PATIENTS TREATED WITH PLACEBO AND FIVE DRUGS

Source of variation	Sum of squares	Degrees of freedom	Mean squares	F ratio	Significance level
Patients	1 1463	12	0 1206	35 7	Highly significant
Placebo *v* drugs	0 0133	1	0 0133	3 93	$P = 1/20$
Between drugs	0 0267	4	0 0067	2 00	$P \simeq 1/10$
Residual	0 2029	60	0 00338		
Total	1 3892	77			

The results of an analysis of variance (table II) indicate that, though the patients were the major source of variation, the drugs (the four bronchodilator drugs plus phenobarbitone) exerted a significant influence on F E V$_{1 0}$ values, furthermore there is evidence that some drugs exerted a greater effect than others *This method of analysis* ignores the order in which the drugs were taken and the question of whether the influence of a given drug is in some way manifest for a week or more *after it has* been stopped We have assumed that these factors are unimportant

Table III shows the percentage changes in F E V$_{1 0}$ values for each drug in relation to the placebo values computed from the analysis of variance The upper and lower limits are shown between which the probability is 0 95 that the true percentage change lies The appearance of the geometric rather than the arithmetic mean is the result of logarithmic transformation of the data The procedure is an approximation, since same bias is involved in reverting from logarithmic values It may be concluded that, though the drugs in general seemed to have a slight favourable effect on the F E V$_{1 0}$ under the conditions of the experiment, only aminophylline suppositories and choline theophyllinate showed a demonstrable individual effect

In fig 1 the individual values for F E V$_{1 0}$ are shown for all the patients, the results being expressed as percentages of the values obtained after treatment with the placebo The influence of aminophylline suppositories and of choline theophyllinate is apparent The changes with sublingual isoprenaline *are inconsistent, but a small* and relatively consistent effect of theodrox is suggested The confidence limits cited in table III are based on the overall variation Since the variation is much less in the results for patients taking theodrox, it is likely that the confidence limits for this drug are somewhat narrower than those shown

The scores for each drug, based upon the patients' opinions, are set out in table IV Preliminary analysis showed no evidence that the scores were influenced by the order in which the drugs were taken The results indicate that the patients "identified" the placebo, and that their opinions were probably favourably influenced by all the drugs except isoprenaline *The outstanding* finding is the patients' appreciation of phenobarbitone, this was the only drug which no patient considered "did not suit him" and on which no patient felt he had deteriorated

TABLE III—PERCENTAGE INCREASE ON PLACEBO VALUES ABOUT GEOMETRIC MEAN *

Drug	*Mean*	95 % confidence limits	
		Upper	Lower
Aminophylline suppositories	+16	+29	+5
Choline theophyllinate	+13	+25	+2
Theodrox	+ 6	+16	−4
Sublingual isoprenaline	+ 5	+17	−5
Phenobarbitone	+ 3	+15	−7

* The use of the geometric mean is due to the logarithmic transformation

The relationship between the patients' opinions for each drug and changes in the values of F E V$_{1 0}$ is shown in fig 2 for the 13 patients for whom both sets of data were available The chief finding is that patients who felt greatly improved by any drug showed a mean increase of 32% in F E V$_{1 0}$ The patients tended to give lower

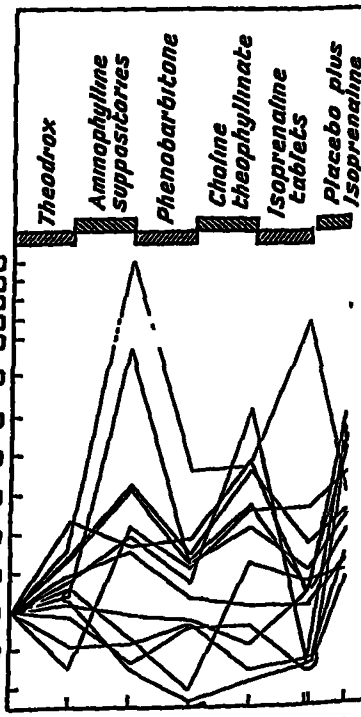

Fig 1—Changes in F E V$_{1 0}$ expressed as percentage of *placebo* value, at end of one week's *treatment* with each trial drug and, at extreme right, after inhalation of 1% isoprenaline during treatment with *placebo*

TABLE IV—PATIENTS' OPINIONS OF TRIAL DRUGS

Drug	Mean score	No. of patients having a score of			
		−1	0	+1	+2
Placebo	−0·07	4	8	3	0
Aminophylline suppositories	0·60	2	6	3	4
Choline theophyllinate	0·67	1	6	5	3
Theodrox	0·67	2	3	8	2
Sublingual isoprenaline	0·13	6	2	5	2
Phenobarbitone	0·73	0	6	7	2

The standard error of the difference between two means is 0·32, the calculation being based upon the residual mean square (0·786) of an analysis of variance.

scores for aminophylline suppositories than might have been anticipated from their improved F.E.V.$_{1\cdot 0}$ values. Our impression, based on their verbal comments and questionnaire replies, is that this was related to their dislike of the method of administration. Possibly the scores for isoprenaline tablets were influenced by the palpitations which sometimes developed. However, in one or two instances, the reason for lack of correlation between the patient's opinion and change in F.E.V.$_{1\cdot 0}$ was that the opinion was based on experience over a week, of which the F.E.V.$_{1\cdot 0}$ was not representative.

Discussion

In view of the finding that the response to inhaled isoprenaline is a complex function of the initial F.E.V.$_{1\cdot 0}$ (Hume and Gandevia 1957b) it is necessary to examine the validity of using changes in F.E.V.$_{1\cdot 0}$ to compare the effects of different drugs at different times. The relationship existing is such that, as the pre-inhalation values for F.E.V.$_{1\cdot 0}$ rise from the low levels associated with severe wheezing, so does the response to isoprenaline (both the initial level and the response being expressed in litres). There is a sharp peak of maximal response after which the response tends to decrease progressively, the post-inhalation value for F.E.V.$_{1\cdot 0}$ tending to remain constant. If a similar relationship exists for all bronchodilator drugs, irrespective of the route of administration, it may be unjust to compare the response to one drug on one day with the response to a second drug some time later. A spontaneous alteration in the initial level of the F.E.V.$_{1\cdot 0}$ in the group of patients studied may conceivably place one drug at a distinct disadvantage.

In the present investigation it is likely that the latin square design will have eliminated this factor as a cause of serious error. In any event the effect described would tend to blur the comparisons between drugs; yet we have been able to show significant differences between them.

The objective assessment provided by the F.E.V.$_{1\cdot 0}$ indicates that, under conditions of outpatient practice, choline theophyllinate and aminophylline suppositories are reasonably effective bronchodilators, the improvement produced being rather less than the immediate response to an isoprenaline aerosol. The possibility that some patients respond to one drug but not to another remains likely, but the effect of this in a small series is to diminish the chances of showing that any drug is effective at all. In so far as significance can be attached to the results in a single person, fig. 1 shows that 1 patient responded to choline theophyllinate but not to aminophylline suppositories, and 1 did the reverse. Fig. 1 also suggests that the trial series included 4 or 5 patients relatively unresponsive to all the antispasmodics tried, despite the fact that a prerequisite for inclusion in the trial was an improvement of more than 10% in F.E.V.$_{1\cdot 0}$ after an inhalation of 1% isoprenaline. 3 of these patients had been diagnosed as having emphysema, but the group showed no well defined distinguishing features clinically. Previous therapy with the trial drugs may have produced some drug resistance.

The patients' approval of phenobarbitone is of interest not only from the therapeutic point of view but also because of the light it throws upon the significance of the patients' opinions about their well-being. We believe that the search for objective methods of assessment has led to the patients' views being too often neglected and regarded as valueless. Phenobarbitone was deliberately included in the trial in an attempt to obtain, as it were, an objective assessment of the meaning of these opinions. Our results suggest that phenobarbitone is a satisfying drug for these patients, who probably tend to be anxious and introspective, in spite of its lack of definite effect on ventilatory capacity. It follows that, in assessing their own progress, these patients are influenced by sensations other than those of wheezing and dyspnœa, even when they know that their ability to breathe is the subject of a special study. That their opinions are also related to changes in their ability to breathe is indicated by the high values found for F.E.V.$_{1\cdot 0}$ when they were feeling "much better." From the present figures and from other observations it seems possible that an improvement of more than about 10% in F.E.V.$_{1\cdot 0}$ over a week can be reflected in a patient's opinion, but only if the drug used has no undesirable properties; an increase of this order is certainly appreciated when it is produced over a few minutes with a suitable aerosol.

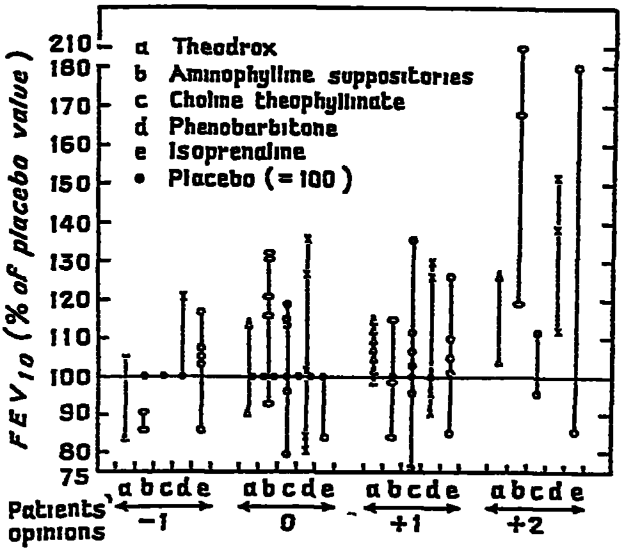

Fig. 2—Relationship between F.E.V.$_{1\cdot 0}$, expressed as a percentage of placebo value, and patient's opinion of his progress expressed in grades (−1 to +2: see text).

The influence of personality on a patient's opinion about his progress is well known.

Although we made no deliberate study of this factor, it was well illustrated by 1 patient, a most coöperative but uncommunicative, almost morose, man, who felt that four of the six treatments made no difference and two made him worse. One of the latter was associated with an increase of 20% in F.E.V.$_{1\cdot 0}$ and two of the former with an increase of over 30%; on these occasions clinical improvement was obvious at a glance.

More or less systematic errors of opinion are not important in comparative trials of this type. More important are those who are bad observers, suggested by the variability of their opinions. The existence of this group determines the necessity for relatively large series to obtain significant results. The observer conducting the tests gained the impression in conversation that the knowledge that they were taking part in an experiment made the patients more frankly critical of the drugs than were patients attending a routine clinic. This is of no significance in the circumstances of the trial but may be relevant in relating our findings to clinical practice.

In summary it is clear, from the present study of 15 patients, that not only are the patients' opinions complementary to objective methods but also the patients are successful in distinguishing between treatments The opinions of somewhat larger groups can achieve the more difficult feat of discriminating between two forms of breathing exercises, their distinction being supported by such objective assessments as were made (Bolton et al 1956)

Conclusion

The conclusion reached from this investigation is that, excluding hormonal therapy and under conditions of outpatient practice, the most satisfactory symptomatic treatment of wheezing dyspnœa at present available is likely to be a combination of one of the more effective bronchodilators with small daily doses of phenobarbitone The need for dual therapy in some form is emphasised when the effective drug is likely to be unpopular for any reason

Summary

On a latin-square experimental design four commonly prescribed bronchodilators, phenobarbitone, and a placebo were given for a week each to 15 patients complaining of wheezing dyspnœa associated with asthma, bronchitis, or bronchitis and emphysema The effects of these drugs were assessed in terms of the patients' opinions and the forced expiratory volume at one second

The patients' opinions distinguished the placebo and were favourably influenced by phenobarbitone and three of the bronchodilators

The changes in forced expiratory volume at one second showed that, though the drugs in general were producing a favourable response, only aminophylline suppositories and oral choline theophyllinate appeared reasonably reliable and effective in the dosages used

The significance of the patients' opinions is discussed in the light of these findings, and the complementary nature of the subjective and objective assessments is emphasised

We are indebted to Dr J G Scadding and to members of the consultant staff of the Brompton Hospital for permission to study their patients, and to the patients and their general practitioners for their willing coöperation Our thanks are also due to Dr P Armitage, in particular, for statistical advice and assistance, and to Mr S Powlson, chief pharmacist, for his help in distributing the drugs

A PARTICULAR form of infantile cirrhosis of the liver reported from Jamaica (McFarlane and Branday 1945, Hill 1951, Hill et al 1953) differs in several respects from the mild hepatic injury seen in kwashiorkor The morphological picture in this infantile cirrhosis is dominated by an obliterating lesion—veno occlusive disease (Bras et al 1954)—of the medium sized and smaller ramifications of the hepatic veins with non portal cirrhosis as the ultimate result The essential pathology of veno occlusive disease was described in this journal by Bras and Hill (1956)

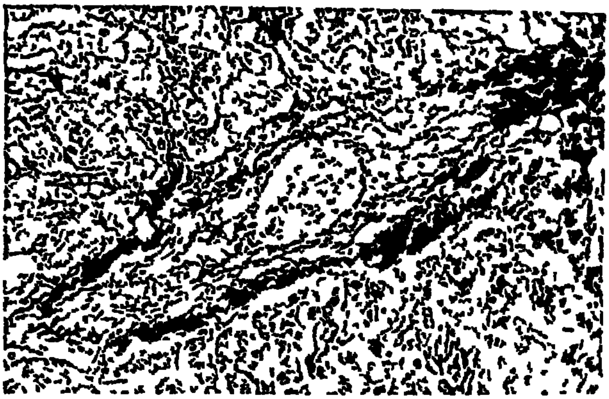

Fig 1—Occlusive lesion in branch of hepatic vein in cow dead from veno occlusive disease (Mallory trichrome stain ×107)

The toxic origin of veno-occlusive disease was originally suspected by McFarlane and Branday (1945) The practice of making a decoction of the leaves of various plants and consuming the resultant liquids (bush tea) is well established in Jamaica and neighbouring islands as a remedy for ailments and otherwise

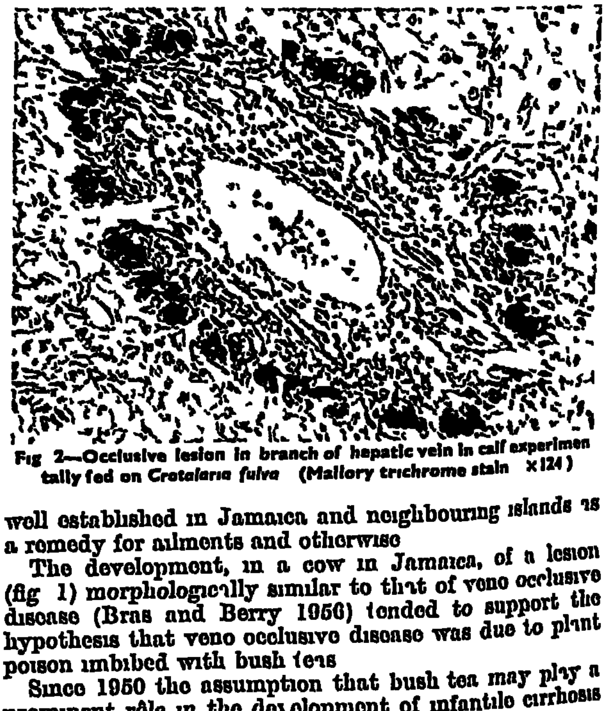

Fig 2—Occlusive lesion in branch of hepatic vein in calf experimentally fed on *Crotalaria fulva* (Mallory trichrome stain ×124)

The development, in a cow in Jamaica, of a lesion (fig 1) morphologically similar to that of veno occlusive disease (Bras and Berry 1956) tended to support the hypothesis that veno occlusive disease was due to plant poison imbibed with bush teas

Since 1950 the assumption that bush tea may play a prominent rôle in the development of infantile cirrhosis seen in Jamaica has been tested extensively in experiments on white rats under varying conditions * More recently we have experimented on calves †

It has been known for a considerable time (see Theiler 1920) that senecio (ragwort) is poisonous to horses and cattle and can produce a disease of the liver leading to fibrosis and cirrhosis Willmot and Robertson (1920) and Selzer and Parker (1951) focused our attention on these

---

* These experiments were made in the laboratory of one of us (P G) as part of a collaborative study of the research groups at the University College of the West Indies and the University of Pennsylvania These investigations including those reported here were supported by grants of the Nutrition Foundation and the Josiah Macy jun , Foundation New York

† This part was done in Jamaica and made possible through facilities put at our disposal by Reynolds Jamaica Mines

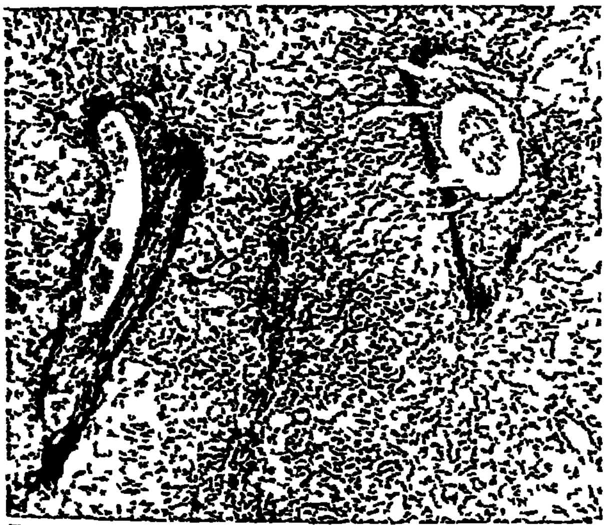

Fig 3—Occlusive lesions in branches of hepatic vein in horse with clinical crotalaria poisoning (Mallory trichrome stain ×47.)

plants, especially since, in the case reported by Selzer and Parker, a pathological lesion was observed in the branches of the hepatic vein. Betty and Markson (1954) and Cockburn et al (1955) have described poisoning with senecio in animals.

On the other hand, observations on veno-occlusive disease in man in Barbados implicated crotalaria (rattlebox) (Stuart and Bras 1956). In the veterinary literature crotalaria poisoning has been described since 1884 (Bessey and Stalker 1884) and has been associated with parenchymatous hepatitis in horses and cattle since 1920 (Theiler 1920). Reports of the toxicity of crotalaria and the incidence of poisoning by it in cattle (Becker et al 1935, Sanders et al 1936), swine (Emmel et al 1935), chickens (Neal and Becker 1933, Thomas 1934), quail and doves (Thomas 1934), and horses and goats (Emmel and Sanders 1942) came from America and from South Africa, India, and Australia (L B Bull, personal communication). Further reports on the toxicity of these plants were given by Piercy and Rusoff (1946) and Gibbons et al (1950). Intensive experimental studies with one of the hepatotoxic pyrrolizidine alkaloids, monocrotaline, present in crotalaria, were made by Ratnoff and Mirick (1948, 1949). Chemically monocrotaline is closely related to a similar pyrrolizidine alkaloid retrorsine, contained in senecio (Adams and Rogers 1939). We are not aware of previous reports of crotalaria poisoning in man.

Material

We report here our findings in a calf fed experimentally on *Crotalaria fulva* and our observations on material kindly sent to us by other investigators working on crotalaria and senecio poisoning. All the animals had obliterative lesions of the hepatic vein similar to those observed in veno-occlusive disease in man.

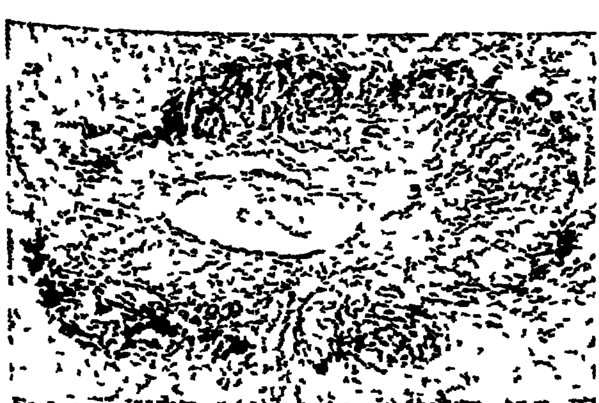

Fig 5—Occlusive lesion in branch of hepatic vein in cow dead from accidental senecio poisoning (Mallory trichrome stain ×87.)

Crotalaria

In 5 calves experimentally fed on *Crotalaria fulva* serial liver biopsies were made at monthly intervals. 4 of these calves died without remarkable histopathological changes in their livers. The 5th calf developed, after six months, an obliterative hepatovenous lesion (fig 2). 5 control calves remained free from change up till eight months after the beginning of the experiment, which was then terminated.

Dr. W J Gibbons kindly sent us material from horses with clinical crotalaria poisoning in which we observed lesions like that shown in fig 3.

Dr L B Bull's material from a horse dead from accidental crotalaria poisoning showed lesions like that depicted in fig 4.

Senecio

Material kindly put at our disposal by Dr L M Markson and obtained from cattle with accidental senecio poisoning displayed vascular lesions perfectly matching those of veno-occlusive disease in man (fig 5). Fig 6 shows a lesion in a horse fed experimentally on senecio by Dr. J Vanek.

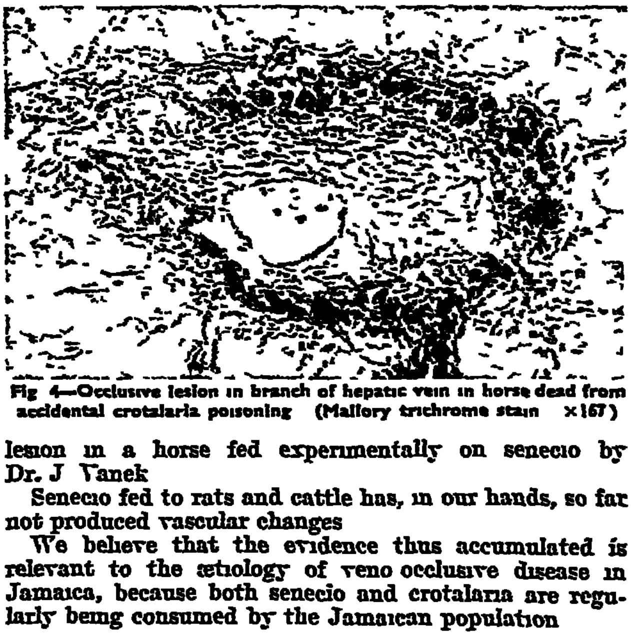

Fig 4—Occlusive lesion in branch of hepatic vein in horse dead from accidental crotalaria poisoning (Mallory trichrome stain ×167.)

Senecio fed to rats and cattle has, in our hands, so far not produced vascular changes.

We believe that the evidence thus accumulated is relevant to the ætiology of veno occlusive disease in Jamaica, because both senecio and crotalaria are regularly being consumed by the Jamaican population.

Discussion

Senecio and crotalaria, both in our hands and in the hands of others, have produced in rats, cattle, and horses

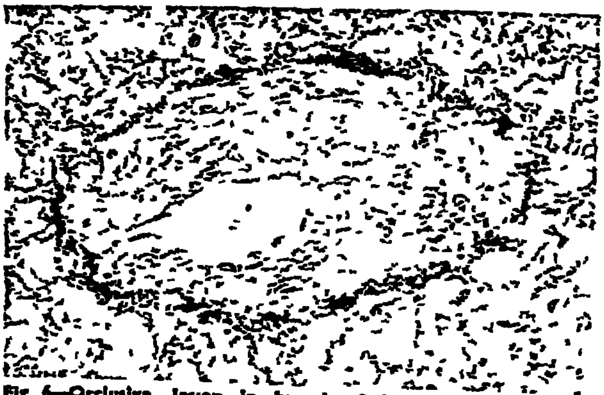

Fig 6—Occlusive lesion in branch of hepatic vein in horse experimentally fed on *Senecio erraticus barbaræfolius* (Mallory trichrome stain ×173.)

much hepatocellular damage The only convincing vascular lesions—i e, obliterating lesions of the branches of the hepatic veins—that we have been able to find published were those pictured by Davidson (1935) after the administration of retrorsine to rats and by Vanek (1956) A comprehensive report by Bull et al (1957) on crotalaria poisoning in horses in Northern Australia gives histopathological observations, including some hepatovenous changes Blood lagoons, with intralobular hæmorrhage and massive central necrosis in the liver lobules, have been described in animals with crotalaria poisoning (Emmel et al 1935, Harris et al 1942, O D Ratnoff personal communication), but no vascular changes

Senecio and crotalaria have pyrrolizidine alkaloids in common, and extensive work on this has been done in Australia (Bull et al 1956) and elsewhere (see Schoental and Head 1955), the damage to the liver being reported as hepatocellular

In our hands *Crotalaria fulva* has produced veno occlusive disease (fig 2), and in material sent to us by other investigators both senecio and crotalaria had produced obliterating lesions of the hepatic veins The importance of the obliterating lesion and its rôle in the production of hepatocellular damage with subsequent fibrosis need further study

In view of the seemingly independent and/or concurrent appearance of hepatocellular damage, on the one hand, and obliterating vascular lesions of the hepatic veins, on the other, we are exploring the possibility that more than one toxin may be responsible for this, each with a different target area The different poisonous substances may well be unequal in concentration and in toxicity and may differ in various parts of the plants and at various times of the plant's life

Summary

It is postulated, on the evidence of experiments with *Crotalaria fulva* on cattle in Jamaica, that herbal infusions made from crotalaria and taken by the Jamaican population for medicinal and other purposes constitute (one of) the ætiological factor(s) in veno occlusive disease of the liver

It appears that a similar rôle is played by senecio

All plants were collected by the Department of Botany, University College of the West Indies, and we are extremely grateful to Prof G F Asprey, Dr J H Palmer, and Prof A D Skelding for their cooperation

We are greatly indebted to Dr W J Gibbons, of the School of Veterinary Medicine, Auburn, Alabama, U S A, Dr L B Bull, of the Commonwealth Scientific and Industrial Research Organisation, Australia, Dr L M Markson, of the Ministry of Agriculture, Fisheries and Food, Veterinary Laboratory, England, and Dr J Vanek of the Karlovy University, Prague, for supplying material

We also thank the Josiah Macy, jun, Foundation, Reynolds Jamaica Mines, the Colonial Medical Research Committee, and the Government of Jamaica for providing facilities for this experimental work

L-NORADRENALINE THERAPY IN ACUTE RENAL FAILURE

D Mattingly*
M B Lond
LATE RESIDENT MEDICAL OFFICER, ROYAL DEVON AND EXETER HOSPITAL

The use of L-noradrenaline in the treatment of hypotensive states was inaugurated by Goldenberg et al (1949) and its successful use has often been reported since The physiological aspects of using noradrenaline as a vasopressor drug have been fully discussed by Von Euler (1955) He laid stress on the importance of starting treatment early, in view of the increasing refractoriness of the blood-vessels to the action of physiologically released or exogenously added noradrenaline during prolonged hypotension 'Levophed,' a solution of L noradrenaline bitartrate, contains 1 mg of active base to each millilitre and is usually diluted with 5% dextrose and given by continuous intravenous infusion

The term "peripheral circulatory failure" has come into use to describe the clinical picture of prolonged hypotension associated with a sluggish peripheral circulation and patchy cyanosis of the extremities It may arise when no blood has been lost, or after apparently adequate restoration of blood-volume when this has been reduced by hæmorrhage or severe dehydration Peripheral circulatory failure has been observed in patients with fulminating infections, intestinal strangulation, acute pancreatitis, coronary thrombosis, pulmonary embolism, chemical pneumonitis, diabetic ketosis, acute adrenal failure, and barbiturate poisoning, and after operations When acute renal failure is already present, or develops as a result of prolonged hypotension, the effect of noradrenaline on the kidneys has to be considered

Nickel et al (1954) and others have shown that in normal people noradrenaline, in doses large enough to raise the systolic blood-pressure by 25–50 mm Hg, produces a reduction in renal blood flow with an increase in urine-flow and in tubular reabsorption of sodium and potassium Nickel et al suggested that at least some of these effects were due to intrarenal vasoconstriction and relative tubular ischæmia Lathem (1956) demonstrated similar results in patients with chronic renal disease These results might suggest that noradrenaline should not be used in hypotensive patients with severe oliguria or anuria, because of the danger of increasing already existing tubular damage On the other hand, restoration of the systolic pressure to normal levels by noradrenaline will increase the renal blood-flow and may well outweigh the local vasoconstrictor effect on the renal vessels In the two cases reported here treatment with noradrenaline led to satisfactory recovery

Methods

All blood samples were collected from a vein. The analytical methods were as follows: sodium and potassium, flame-photometer (Evans Electro selenium Ltd.); chloride, method of Schales and Schales (King 1946); bicarbonate, titration method (Lehmann 1951); urea, urease nesslerisation method (King 1946). All urine samples were collected by an indwelling Foley's self-retaining catheter during the period of oliguria.

Case-reports

FIRST CASE

A woman, aged 63, with no history of renal disease and in otherwise good health, had a vaginal hysterectomy on account of complete procidentia on Nov. 24, 1955. Her preoperative blood-pressure (B.P.) was 170/90 mm. Hg. There was some blood loss at operation, but this was replaced by 2 pints of compatible whole blood at the time and her hæmoglobin next day was 92%.

1st postoperative day.—No urine was passed all day, and she started vomiting during the afternoon. Her daily fluid intake was restricted to 1 litre of distilled water containing 400 g. of dextrose by intragastric drip.

2nd day.—A further litre of the dextrose solution was given during the 24 hours. No fat was included in the drip because it increased the nausea and vomiting. Only 350 ml. of urine was collected by catheter. Blood was taken daily from now on for electrolyte and blood-urea estimations (table I). The patient was nursed in isolation and started on a single daily injection of a million units of crystalline penicillin. Parenteral ascorbic acid and vitamin-B complex were also given.

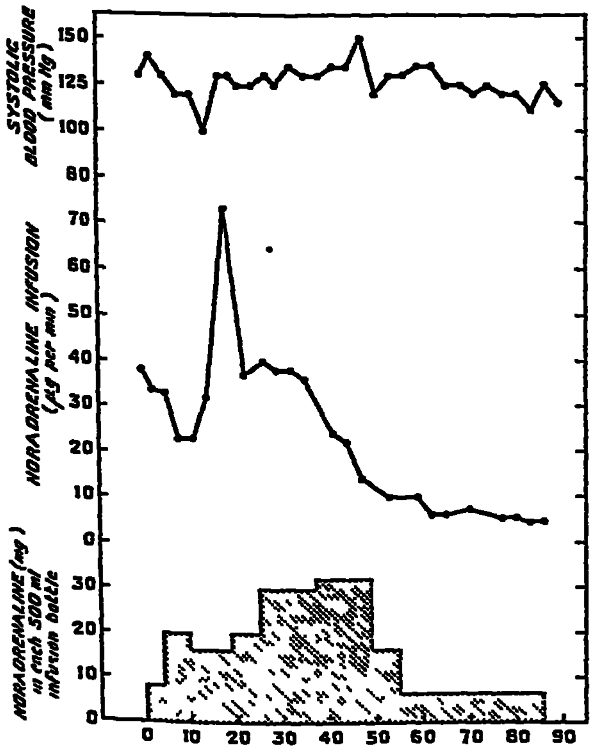

Fig. 1—Case 1: systolic blood-pressure; rates of infusion of noradrenaline; and amounts of noradrenaline in each 500-ml. infusion bottle.

3rd day.—During the night profuse watery diarrhœa developed. Her fluid intake was increased, but she continued to pass a lot of fluid per rectum and by the afternoon was in peripheral circulatory failure with an unrecordable B.P. She was now clinically dehydrated, but the rapid intravenous infusion of 2 litres of physiological saline solution and 2 pints of plasma had no effect on her B.P. Intravenous methylamphetamine hydrochloride ('Methedrine') 25 mg. was also without effect, and, as the patient was now moribund, noradrenaline (levophed) was added to the infusion fluid producing a rapid rise in her systolic pressure to 130 mm. Hg. The blood-pressure was maintained about this level, by adjusting the drip and altering the amount of noradrenaline in the infusion bottles, for several days (fig. 1). Through another vein a further 2 pints of compatible whole blood was given. She was now anuric again with a blood urea of 215 mg. per 100 ml.

4th day.—The intragastric drip was continued, but with a reduced dextrose content of only 100 g. per litre, for it was found that higher concentrations caused vomiting and diarrhœa. Fluid balance was difficult to estimate, for an unknown quantity of fluid—probably several litres—had been lost per rectum. Since this loss had now stopped, and she was no longer clinically dehydrated, the daily fluid intake was restricted to 1 litre by intragastric drip and intravenous infusion. In addition, water and later very weak tea were given by mouth equal in amount to her urinary output of the previous 24 hours (fig. 2). It was thought that the patient might be deficient in potassium because of the diarrhœa, and this was confirmed by a plasma level of 3·2 m.eq. per litre and also suggested by an electrocardiogram, the QT_c interval being prolonged to 0·48 sec. About 50 m.eq. of potassium, in a mixture of potassium salts, was added daily to the intragastric

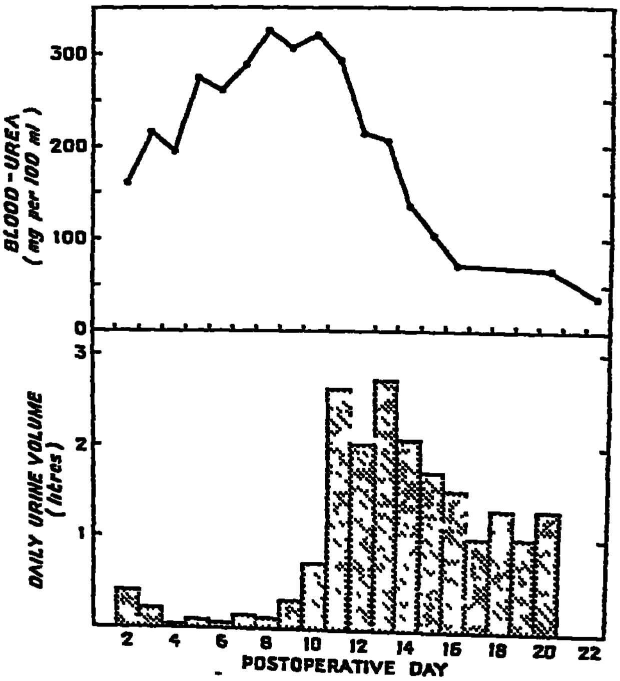

Fig. 2—Case 1: blood-urea levels and daily urine output (urine collections after the 14th day incomplete).

drip Her general condition had improved, but her temperature had risen to 101°F and fæcal culture had produced a strong growth of *Staphylococcus aureus* She was therefore given oral erythromycin 400 mg 6 hourly, since it was suspected, and later confirmed, that this organism might be resistant to other antibiotics Her fever settled in a few hours The amount of noradrenaline required to maintain her B P, which had risen to 73 µg per min, now began to fall

5th and 6th days —Oliguria persisted and the urine contained many red and white blood cells A strong growth of *Staph aureus* was obtained on culture, though by now fæcal swabs were sterile and the temperature normal The blood urea rose to 260 mg per 100 ml, but the nausea and vomiting had ceased The patient was very drowsy, sleeping most of the day The plasma potassium level was now within the normal range

7th day —The noradrenaline infusion was stopped when the infusion rate had fallen to 4 µg per min It had run for 86 hours without complications or obvious side effects, and through the same vein for over 80 hours

8th to 22nd days —The erythromycin was discontinued after a total dose of 5 6 g Fluids were restricted until diuresis started on the 11th day, adequate amounts were then given to compensate for the increasing urinary losses A low-protein, high-carbohydrate diet, with additional sodium and potassium, was then started and steadily increased to a normal ward diet by the 22nd day No renal function tests were carried out, but proteinuria persisted for some weeks afterwards

SECOND CASE

An obese man, aged 49, developed polyuria and polydypsia, and lost two stone in weight in 6 weeks He was admitted in a drowsy, confused state with diabetic ketosis and a blood-sugar of 800 mg per 100 ml Despite massive doses of insulin and intravenous saline, he became oliguric and pulseless, his blood urea rising to 160 mg per 100 ml A noradrenaline drip was started and the systolic pressure rose rapidly to 130 mm Hg, where it was maintained by a concentration of about 20 µg per min His urine output increased and he recovered completely after receiving 3200 units of soluble insulin and 12 litres of intravenous fluids during the first 12 hours of treatment

Discussion

The first patient did not become dehydrated until after the profuse diarrhœa on the 3rd postoperative day, this cannot have been the cause of the previous oliguria and raised blood-urea, though it may have contributed to the renal damage (Oliver et al 1951) Treatment was based on restriction of fluid and electrolyte intake until diuresis started (Bull 1955), and, apart from giving oral potassium when the serum level fell to 3 2 m eq per litre, the temptation to try to adjust the serum electrolyte levels towards normality was resisted during the oliguric phase The minimum 1600 calories a day was not achieved because the patient could not tolerate the high concentrations of intragastric dextrose and peanut oil to provide this For several days she did not receive more than 400 calories a day A direct infusion of a concentrated dextrose solution into the inferior vena cava (via a femoral vein) was thought to be contra indicated because of severe *Staph aureus* infection Peripheral circulatory failure developed at the onset of the fulminating staphylococcal enteritis The enteritis responded slowly to oral erythromycin Intravenous methylamphetamine failed to raise the B P, as Downie (1954) found when treating a patient with postoperative peripheral circulatory failure Similar negative results have been reported with dexamphetamine sulphate Methylamphetamine raises the B P by increasing the cardiac output, at the same time lowering the peripheral resistance (Churchill Davidson 1951), it would therefore not be expected to be effective in the treatment of peripheral circulatory failure On the other hand, noradrenaline produced an immediate rise in the systolic pressure, which was maintained by a continuous intravenous infusion Therapy was complicated by the need to restrict the total fluid intake to about a litre a day The infusion ran for 86 hours without any complications or side effects Diuresis started after 10 days of severe oliguria (fig 2)

In the second patient noradrenaline produced an immediate rise in B P, followed by a considerable increase in the urine output Noradrenaline produces a fall in renal blood-flow and an increased urinary output in normal people (Nickel et al 1954), but it seems more likely that the increased urinary flow in this patient was primarily due to restoration of the B P to normal levels Oliguria is not uncommon in hypotensive states, and a similar restoration of normal urinary flow was seen in two cases of barbiturate poisoning treated with noradrenaline (Mattingly 1955) It is impossible to prove that noradrenaline had no deleterious effect on these patients' kidneys, but it is equally certain that without it neither would have survived The theoretical dangers and toxic effects of L noradrenaline infusions have been surveyed by Ritchie (1956) In a small series of cases the only "toxic" effect observed was excessive sweating, which appeared only with high concentrations Local tissue necrosis was avoided in the first case by inserting a 'Polythene' tube several inches up an ankle vein and tying it in, this vein was used continuously for over 80 hours, watch was kept for the bluish discoloration of the overlying skin which is the first sign of impending trouble The second patient received an infusion through a needle in a superficial arm vein After some hours bluish discoloration developed, with obvious leakage into the surrounding tissues Fortunately it was possible to discontinue the noradrenaline at this point and there was no sloughing

Dosage

Little guidance is given in the literature as to the dosage of noradrenaline required to restore the blood pressure to normal levels in patients with peripheral circulatory failure

The dosage depends on the amount of noradrenaline in the infused solution and on the drip rate Ritchie (1956) states that the correct dosage is that which raises the pressure to the desired level and maintains it there There is, however, considerable difference of opinion as to what are desirable levels It seems reasonable to suspect peripheral circulatory failure if the systolic pressure falls below 100 mm Hg (Downie 1954), and to aim at raising it to about 130 mm Hg The amount of noradrenaline needed to achieve this varies widely from patient to patient Nickel et al (1954) used 12-15 µg per min in normal people to raise the systolic pressure by 25-50 mm Hg, and Lathem (1956) found that similar amounts were necessary in patients with chronic renal disease Much larger amounts—up to 72 µg per min —were required in some cases

For hypotensive states Goldenberg et al (1949) recommended not more than 0 36 µg per kg body weight per min, and Martindale (1952) suggests 6-8 µg per min administered in 1 5-2 0 ml per min In the present case 1, who required nearly 40 µg per min initially, such a dilution would have involved infusing 10 ml per min, or 600 ml an hour, and gross over hydration would have resulted De Swiet (1955) found it necessary to increase the dosage to 150 µg per min over two periods of 8 hours when treating a patient with pulmonary embolism There is no evidence that such a high dosage is dangerous provided the blood pressure is watched

Von Euler (1955) reports a case of phæochromocytoma in which as much as 9000 µg per 24 hours was excreted, probably corresponding to a release into the circulation of about 200 mg, or 140 µg per min In the average case of peripheral circulatory failure the initial dosage of noradrenaline required will range from 10 to 30 µg per min, but larger amounts may be needed, particularly if treatment is delayed and the vessels become increasingly refractory

The only real criterion of effective dosage is the fairly rapid rise of the systolic pressure, within a few minutes to about 130 mm Hg If no response is obtained the concentration of noradrenaline in the infused solution should be doubled or trebled to avoid overhydration

The management of these cases, once it has been decided to administer noradrenaline depends on two factors.

(1) The amount of intravenous fluid that can safely be given. Table II shows the relationship between drip rate and daily fluid intake. Not more than 0.6 ml per min should be given if the patient is anuric. For simplicity 20 drops has been taken to equal 1.0 ml, which is approximately correct for most drip sets. A more accurate relationship can be established by dripping the infusion solution into the barrel of a 2 or 5 ml syringe.

TABLE II—SUGGESTED RATE OF INFUSION, DEPENDING ON CLINICAL STATE OF PATIENT

Clinical state	Litres per 24 hr	Ml per min	Drops per min
Anuria, heart failure	0.8	0.6	12
Hydrated, normal renal function	2.4	1.8	36

(2) The initial concentration of noradrenaline to restore the blood pressure must be assessed beforehand. Table III provides a rough guide which has proved useful in practice.

TABLE III—SUGGESTED RATE OF ADMINISTRATION OF NORADRENALINE WHEN STARTING INFUSION

Clinical state	Systolic B.P. (mm Hg)	Noradrenaline (µg per min)
Early circulatory failure	More than 60	10
Severe protracted hypotension	Less than 60	20
Pulseless	Unrecordable	30

Only when these two factors have been decided is it possible to calculate the amount of noradrenaline to add to the infusion bottles.

For example, an anuric, pulseless patient will probably need 30 µg per minute in not more than 0.6 ml of fluid. It will be necessary to add 24 mg of noradrenaline to 500 ml of 5% dextrose to achieve this dosage at this drip rate.

To facilitate these calculations the noradrenaline dosage chart shown in fig. 3 was devised. The diagonal lines represent the amount of noradrenaline in mg which must be added to 500 ml of intravenous fluid at varying noradrenaline concentrations and drip-rates. They are spaced at 2 or 4 mg intervals, these being the contents of the ampoules supplied. Once the systolic pressure has been raised to about 130 mm Hg, and maintained there by adjusting the drip-rate, the actual rate at which noradrenaline is being given can be read off the chart. This enables future requirements to be assessed. If the drip-rate and systolic pressure are recorded by the nurses at half-hourly intervals once the systolic pressure has settled, it is possible to calculate the changing dosages of noradrenaline being used and prepare the next bottle well in advance. When the dosage has fallen to about 5 µg per min the drip can be discontinued to see if the blood-pressure is maintained spontaneously.

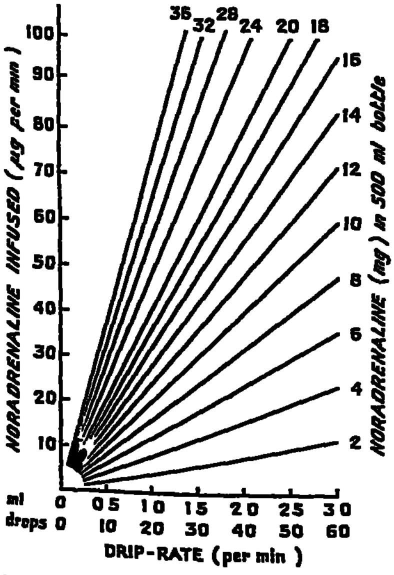

Fig. 3—Noradrenaline dosage chart. Diagonal lines represent millilitres of levophed in each half litre bottle since each millilitre contains 1 mg of active noradrenaline base. Using the appropriate line, the rate at which noradrenaline is being used can be read off the graph, provided the drip-rate is known.

Fluid Vehicle

Because L-noradrenaline breaks down in an alkaline medium, it should be given in 5% dextrose (West 1952) or dextrose saline. If intravenous physiological saline, blood, plasma, or antibiotics are to be given it is probably wise to give these into another vein, despite the added discomfort to the patient (Ritchie 1956). If this is impossible, the two infusion sets can be linked by a glass Y-piece near the vein. It is important to adjust the relative heights of the infusion bottles to prevent reflux of one solution up the other tube. Alternatively, the L-noradrenaline can be introduced into the other drip tube through an intramuscular needle inserted near the entry into the vein.

Steroid Therapy

Peripheral circulatory failure in patients in addisonian crisis, hypopituitary coma, or myxœdema coma may respond to intravenous hydrocortisone alone. If, however, hypotension persists, it seems reasonable to use noradrenaline as well.

Ramey et al. (1951) have shown that adrenal cortical extracts potentiate the blood-pressure response of adrenalectomised dogs to noradrenaline, and Fritz and Levine (1951) have shown that, in adrenalectomised rats, the refractoriness of the blood vessels of the mesoappendix to noradrenaline is abolished by adrenal cortical extracts, but not by deoxycortone. In man, Howland et al. (1956) have treated hypotension during operation with intravenous hydrocortisone and restored the blood pressure to near normal levels. They believe that prolonged hypotension which fails to respond to vasopressor drugs is a sign of adrenal cortical insufficiency. But only one of the seven patients reported was given noradrenaline, and it is doubtful if the dosage was adequate.

If patients fail to respond to a reasonable concentration of noradrenaline, or become refractory to it later, it would seem logical to assume that adrenal insufficiency has supervened and to try to restore the responsiveness of the vessels by steroid therapy. This can be done most rapidly by infusing 100 mg of hydrocortisone in 500 ml of 5% dextrose, following this with further cortisone by mouth or intramuscularly. Steroid therapy should be continued until the patient has been weaned off noradrenaline, and then slowly withdrawn.

Summary

Two cases of peripheral circulatory failure with impaired renal function are reported. Both patients recovered after hypotension had been treated with noradrenaline.

It is suggested that with administration of noradrenaline the increased renal blood-flow following restoration of normal blood-pressure more than compensates for the local vasoconstrictor action of this drug on the renal vessels.

I thank Mr P. M. G. Russell for permission to report the first case, and Dr C. M. Seward for permission to report the second case and for advice and criticism, Miss M. M. McCready for all the biochemical estimations, and the nurses of the Royal Devon and Exeter Hospital for their coöperation in treating these patients.

MASSIVE HÆMORRHAGE IN CHRONIC CONGESTIVE HEART-FAILURE FOLLOWED BY SODIUM DEPLETION

C T G Flear
M B , B Sc Birm
MEDICAL REGISTRAR

Molly Hill*
M B Birm
LATE HOUSE PHYSICIAN

QUEEN ELIZABETH HOSPITAL, BIRMINGHAM

A patient with congestive cardiac failure had a massive hæmorrhage into her right pleural cavity after a thoracentesis Transfusion, with an amount of blood calculated to be about equal to that shed into the chest, was not followed by clinical improvement Cortisone was given and later salt The patient recovered, but died six weeks later from a pulmonary embolus

Case-report

A woman, aged 49, had an attack of rheumatic fever at the age of 7 years, after which she was well and led a normal active life until 1945, when her ankles began swelling and she was becoming rather tired Intermittently thereafter her ankles became swollen, and in 1947–48 she was becoming short of breath on exertion This gradually increased, and she was first seen as an outpatient in 1950, since when she had been taking digitalis At that time she was diagnosed as having mitral stenosis and incompetence and aortic incompetence with auricular fibrillation

She had been admitted to hospital in November, 1953, in congestive cardiac failure and with a right pleural effusion In the next two years she was in hospital seven times, and on each occasion she was in congestive failure with distended neck veins, œdema, and a massive right pleural effusion On the last three admissions she also had ascites Both pleural and ascitic fluids were tapped on each occasion, sometimes more than once Over this period 43 1 litres of fluid was removed

Since 1951 the patient had been given regular injections of a mercurial diuretic and since 1954 ammonium chloride 1 g three times daily

In March, 1955, her total exchangeable body potassium was estimated by using the radioactive isotope ^{42}K (Flear et al 1957) and found to be significantly lowered, and since then she had been receiving potassium chloride 1 g by mouth three times daily In view of the protein loss incurred by the recurrent tapping of effusions (more than 840 g) the patient was given ' Casilan ' and advised to take one or two eggs each day in addition to her meals She was finally admitted on Jan 26, 1956, because of congestive cardiac failure with considerable ascites, right pleural effusion, and œdema of the legs and the sacral regions Her neck veins were distended to the level of the angle of the jaw when she sat up

On admission her hæmoglobin was 11 4 g per 100 ml , serum urea 48 mg per 100 ml , serum sodium, serum potassium, and serum chloride 134 0, 4 6, and 99 0 m eq per litre respectively, serum albumin 4 2 g per 100 ml , and serum-globulin 1 8 g per 100 ml Electrocardiography confirmed the presence of auricular fibrillation, rate about 90 a minute, and showed depression of the S–T segment in leads 2, 3, VF, and V4–6 Chest radiography showed a massive right pleural effusion occupying most of the right hemithorax, displacing the heart to the left, and almost completely obscuring the underlying lung

Treatment

As on her previous admissions she was given anticoagulant therapy During the seventeen days following her admission three thoracenteses and one abdominal paracentesis were done, 13 7 litres of fluid being withdrawn in this way, 8 5 litres of it from the chest During this period her weight decreased by 21 lb

After the third thoracentesis a considerable pleural effusion still showed on radiography of the chest , so a fourth thoracentesis was done at 4 P M on Feb 12 (day 0 in the accompanying table and figure) Towards the end of the aspiration the fluid was bloodstained

Progress

Her pulse rate and blood pressure remained steady over the next six hours Next morning, eighteen hours later (at 10 A M on day 1), she collapsed She had not been too well during the night, and her pulse had been a little weaker than usual at 7 A M and again at 9 A M She was sweating profusely and was extremely pale She was cold, her blood pressure was unrecordable, and her radial pulses were impalpable Her heart rate, counted at the apex, was 160 a minute Her peripheral veins were collapsed and did not fill easily when obstructed by digital pressure, and her respirations were rapid She was, however, fully conscious and coöpera-

* Day of thoracentesis.
† Serum total osmolarity = 305 m. osmol per litre.
Sugar was absent from all urine passed.
Occasional red cells were seen in urine passed on day 3 only; casts in urine passed on days 3 and 4.
Albumin +– in some of the urine passed on days 3, 4, and 5, and + on days 6, 7, 8, and 9.

tive. Her right chest was dull to percussion all over, and it was obvious that she had bled into the pleural cavity. Her hæmoglobin had decreased to 6.7 g. per 100 ml., and her prothrombin activity was 33%. Intravenous vitamin K_1 10 mg. was given, followed by intramuscular vitamin K_1 10 mg. t.i.d., and a blood transfusion was started with some difficulty through two drips with pumps attached to each. Owing to venous constriction it took twelve hours to give the first 8 pints. At first the patient responded well, her colour began to improve, her pulse became palpable at the wrists, and her blood-pressure rose to 80/50 mm. Hg. Her heart rate fell to about 95 a minute. She relapsed in the early hours of day 2, when her trachea was displaced to the left and her breathing was more difficult. She was also somewhat cyanotic, and her heart rate was 130 a minute. Thoracentesis was done and 1.5 litres of fluid, containing hæmoglobin 7.2 g. per 100 ml. was withdrawn. This was followed by improvement in her general condition, and a further 1.5 litres was withdrawn later in the day.

By 9 A.M. on Feb. 14 (day 2) twelve bottles of blood had been transfused, and she was being given her thirteenth; but she remained collapsed. Her face was still pale, though much less so than twenty-four hours previously, and her hands and feet were cold and cyanotic. She was still sweating profusely. Her neck veins were distended to the angle of the jaw on the right side but only half-way up her neck on the left (the level to which they had been before Feb. 12 (day 0)). She appeared moribund though still fully conscious and oriented. Her radial pulses were again impalpable, and her blood-pressure could not be determined. Her heart rate was 130 a minute. No more blood was transfused, because it was thought that the blood lost into the chest had been replaced. Her hæmoglobin was 17.5 g. per 100 ml. in venous blood and 20.1 g. per 100 ml. in capillary blood. She was given cortisone 200 mg. a day by mouth, and this was followed, during the next six hours, by improvement in her clinical condition and peripheral circulation.

Further improvement took place over the next seventeen hours, particularly in the circulation to the extremities; but, by 10 A.M. on day 3 it was still impossible to record her blood-pressure and to detect her radial pulses. Her hands were now warmer and pinker, and there was a quick return of blood to areas blanched by pressure.

Her radial pulses, which had been absent for fifty-six hours, returned by 9 A.M. on day 4, when her blood-pressure, unrecordable up to then, was 90/55 mm. Hg. By this time her twenty-four-hour urinary output, which had been poor, had returned to volumes similar to those before the bleeding. The table records data relevant to kidney function. The heart rate was then 90 a minute. Later on day 4 and on day 5, however, her heart rate rose to 120 a minute. The serum-sodium level on day 4 was low (118 m.eq. per litre) and serum-urea level 138 mg. per 100 ml.

On days 5 and 6 her heart rate increased and her general condition deteriorated, and on day 6 she had mental confusion and drowsiness and felt weaker. It was estimated (Black 1953) at this stage that she had a sodium deficit of about 670 m.eq., and 178 m.eq. of sodium was given as sodium bicarbonate orally on the night of day 6. Her condition improved, and she was given the remainder of the calculated deficit early on day 7. During day 7 her heart was regular at a rate of 85 a minute. Her serum-sodium level rose to 130 m.eq. per litre and her blood-urea level fell to 34 mg. per 100 ml. During the subsequent days she progressively became much less tired and began to read and to take an interest in her surroundings. The administration of further sodium had no effect on her serum-sodium level or her clinical condition. Her renal function improved (see table), and her general condition nine days after collapsing was better than before her thoracentesis.

Her subsequent course was very good until, six weeks later, she died suddenly after an attack of pain in her chest. No necropsy was done, but she was thought to have had a large pulmonary embolus.

Discussion

It has been routine practice for many years in this ward to maintain all patients with congestive failure on anticoagulant therapy. Many such patients have had repeated aspirations of fluid from accumulations in chest and abdomen, and in none previously has there been any significant bleeding.

In this patient the extent of the bleeding was not recognised until she collapsed, because much of the bleeding took place overnight. Her hæmoglobin at the time of collapse was 6.7 g. per 100 ml., compared with 10.5 g. per 100 ml. the day before (see table), suggesting that there had been considerable hæmodilution. The patient received 13 pints of cross-matched blood, and it is unlikely that the blood lost into her right hemithorax could have been much more than this. After aspiration of about six pints from the thorax there was still obviously much more remaining. More was not aspirated because by then her respirations were not being embarrassed by the effusion, and as it was felt that further aspiration might precipitate further bleeding.

Despite adequate replacement of blood, however, initial improvement was not maintained, and the patient was moribund and pulseless, with unrecordable blood-pressure and pronounced peripheral vasodilatation. Her condition called to mind the picture of experimental "irreversible shock" in animals (Wiggers 1950) which supervenes on blood loss of some duration. Lasche et al. (1951) have reported adrenal insufficiency in chronic heart failure, and it was thought that acute prolonged oligæmia, superimposed on the "stress" of heart failure, might have led to exhaustion of the suprarenal glands. This condition is associated with peripheral vasodilatation (Remington 1951) and hypotension unresponsive to the usual forms of therapy (Steenburg and Moore 1955). Cortisone was given and there did appear to be a general improvement Noradrenaline was not given to raise the blood-pressure, because blood-vessels lose their responsiveness to it in the absence of corticosteroids (Ramey et al 1951, Fritz and Levine 1951, Zweifach et al 1953), which appear to play a permissive rôle in the maintenance of vascular tone (Williams et al 1954) Moreover noradrenaline decreases renal blood flow, which was to be avoided

This patient appeared to have developed, by the fourth to sixth day after bleeding, a true depletion of sodium even though she was in congestive failure with systemic œdema She was sweating profusely for six days and had been taking water by mouth but no significant amounts of sodium In heavy sweating a person may lose several litres a day containing as much as 40–50 m eq of sodium per litre Although the daily urinary excretion of sodium decreased during the period of profuse sweating, a considerable amount of sodium must have been lost Cort and Matthews (1954) have warned that giving sodium to hyponatræmic patients who are in congestive heart-failure and not excreting sodium, and in whom there is already some œdema, may do little more than increase the œdema, as Elkinton et al (1952) found in some patients, although other patients improved with salt, and their œdema did not increase Black and Litchfield (1951) gave salt to patients who had been admitted with congestive failure and in whom œdema had subsided but who had deteriorated clinically and showed low serum sodium levels There was resulting improvement without return of œdema

Accordingly caution was exercised in giving sodium It was, however, followed by clinical improvement in well-being, mental function, and heart rate The serum potassium and serum urea levels fell, and the serum-sodium level rose There was no detectable further increase in œdema, the distension of the neck veins did not increase, and the lung base remained clear

The sodium depletion was probably only relative because, with a similar degree of œdema a year previously, the patient's total exchangeable mass of sodium had been about 360% of the mean normal value (Flear et al 1957) In the presence of œdema and with a serum-sodium level of 118 m eq per litre the body sodium is unlikely to be less than normal The depletion is therefore regarded as an acute lowering of the serum sodium level from the loss of sodium

For a time (days 1–3) the patient passed very little urine in spite of an unrestricted intake of fluids by mouth This was probably partly due to heavy sweating, but some renal damage may have resulted from the early period of oligæmia on day 1, when her blood-pressure was unrecordable for four hours A lowered filtration pressure in the glomeruli may also have been a contributory factor At this stage the blood-urea level was 90 mg per 100 ml and the serum-potassium level 7 5 m eq per litre

Despite the absence of recordable blood-pressure for about sixty hours there was little evidence of any significant damage to the kidneys Thus casts, red blood-cells, and albumin were present in the urine for only a few days The kidneys continued to deal with the electrolytes differentially, and their concentrating power also appeared satisfactory Presumably, in the absence of oligæmia, the renal blood flow, when the blood-pressure was unrecordable, was sufficient to prevent damage from anoxia, just as the cerebral circulation was sufficient to keep the patient conscious, rational, and cooperative

This case draws attention to some of the consequences of delay in replacing lost blood Chronic congestive failure is not a contra-indication to the rapid and complete replacement of blood after hæmorrhage, and in this patient there was never any evidence of a rise in venous pressure or of pulmonary œdema Sodium depletion resulted from excessive sweating, and a full recovery was not made until sodium had been replaced adequately as well as blood

We wish to record our appreciation of the help afforded by Sister V J Humphries and her staff in the care and study of this patient, who was in the care of Dr O Brenner, consultant physician to Queen Elizabeth Hospital, to whom we are indebted for permission to publish and for advice in presentation Dr H J Yardley, late of the department of experimental pathology in the University of Birmingham, kindly undertook estimations of osmolarity Other investigations were made by the departments of biochemistry and hæmatology at the hospital

POTT'S PARAPLEGIA OF FIFTY YEARS' DURATION

B J S Grogono

M B Lond , F R C S

REGISTRAR, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, LONDON ,
LATE SENIOR REGISTRAR, WEST MIDDLESEX HOSPITAL,
ISLEWORTH

THE outlook for a patient with unrelieved Pott's paraplegia is poor at the present time , fifty years ago many would have considered it hopeless The following case is therefore of interest

Case-report

History

Born in 1899, the patient was a normal child until he was 3 years old • But at 3 years 8 months he attended the Royal National Orthopædic Hospital because of weakness of his leg and a feeling of "sand in his shoes" The hospital wished to admit him but his mother could not afford it Instead he was placed on a Bradford frame on which he lay at home for about a year

At the end of this time he could walk a few steps and was sent to a convalescent home He lay there for many weeks in a special box He was very miserable and received no teaching, and returned home about a year later, incontinent and dirty His mother then nursed him until he was 7, when he was admitted to St Thomas's Hospital Two operations for a paravertebral abscess were performed (details not available) The wounds had not fully healed when he went home some months later and he still had paraplegia

In August, 1907, at the age of 8, he was admitted to Cheyne Walk Hospital for Sick and Incurable Children, and for seven years he lay there flat on his back, with weights on his legs and a bottle between them His education was entirely fortuitous, depending on Society ladies who, out of charity, adopted his cot and taught him to read, write, and crochet He still, fifty years later, corresponds with his benefactors

In 1914, after a change of staff in the hospital, he got up in a jacket and gradually became mobilised in a wheel chair This mobilisation, after seven years on his back, took three years, and he was discharged at the age of 18 Three months' convalescence was paid for by his self appointed guardians who also sent a wheel chair By much determination he was able to get around the meadows and keep himself clean He kept careful watch on his bowels and regulated them by noticing the action of his diet, much as a patient with a colostomy controls its action He had a slight warning before defæcation

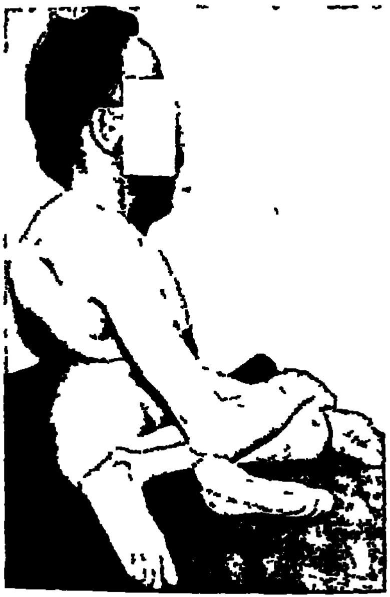

Fig 1—Present condition showing old operation scar over dorsal kyphus and typical posture adopted at rest. The wasting and deformity of the lower limbs contrast with well-developed upper trunk and arms

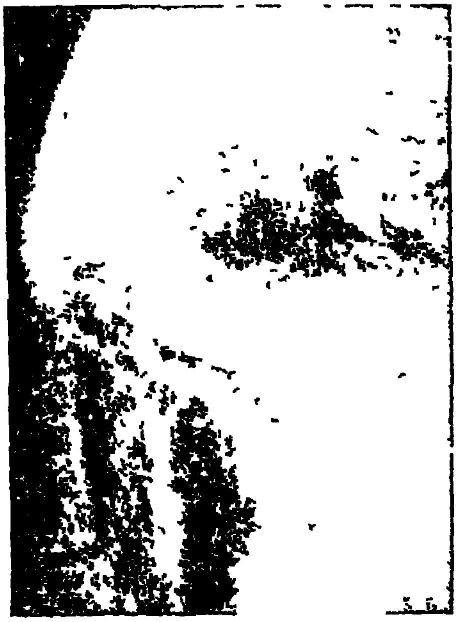

Fig 2—Radiographs of spine Old tuberculous caries of lower dorsal spine and almost complete destruction of T6–12, with marked angular kyphus and an old calcified paravertebral abscess at this level

He returned home in 1917 and remained with his mother till her death in 1952 He was given a typewriter by his sponsors, and taught himself to type with the aid of an instruction book He gradually began to make an income by typing, knitting, and crochet work His health remained fairly satisfactory except for occasions when he was troubled by episodes of loin pain and shivering attacks For these he took aspirin and hexamine tablets, prescribed by his doctor

Some time in 1931, his pain and fever became more severe and his urine cloudy On his own initiative he bought a catheter, carefully cleaned it, lubricated it with soft paraffin carbolic vaseline, and passed it on himself, copying the action he had seen many years before when he had been in hospital Filthy urine escaped, and he was so amazed at the relief that he decided to continue the practice He found that, if he did this night and morning, he was dry between catheterisations and need no long carry a bottle around He continued this until July, 1955, when he was unable to pass his catheter If the bladder was allowed to get over distended, he had flexor spasms of his legs, sweating, and general discomfort This provided some warning but the spasms made catheterisation harder A no 8 catheter was normally used, a no 7 being kept in reserve for difficult occasions

Since 1933, he has led an active life, using a 'Merlin' chair indoors and a wheel chair outside He usually wears a plastic spinal support Since the death of his mother in 1952 he has lived with his brother He has a separate upstairs room and conducts his own affairs He types sections for the *Encyclopædia Britannica* and is secretary of a Bible reading class

He was admitted to the West Middlesex Hospital in July, 1955, with retention of urine after he had failed to pass a catheter

Examination

He was a small, alert, cheerful man in good general health, with a rather pigeon shaped chest but no evidence of pulmonary disease (fig 1)

Spine and upper limbs—He had severe kyphosis in the region of the sixth to tenth thoracic vertebræ, and an irregular linear scar about 6 in long over this region (presumably the site of operations for paravertebral abscess) The upper limbs were well developed

Pelvis and lower limbs—The paralysed lower limbs and buttocks were grossly wasted An irregular scar overlay the left greater trochanter, the site of previous pressure sores The right hip was dislocated with 2 in shortening of the right leg Both hips had 50° fixed flexion deformity, but full

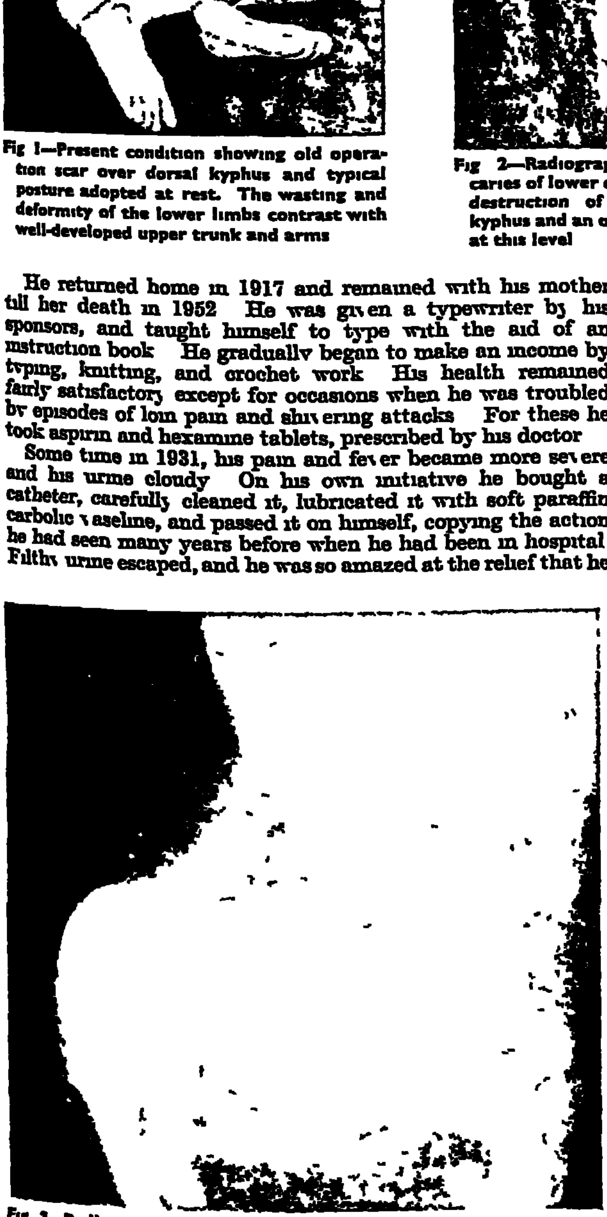

Fig 3—Radiograph of lumbar spine and pelvis The lumbar spine is unaffected but the right sacro-iliac joint shows evidence of old tuberculous disease The dislocated right hip prostatic calculi, and calcified mesenteric glands are clearly shown but no opaque renal calculi

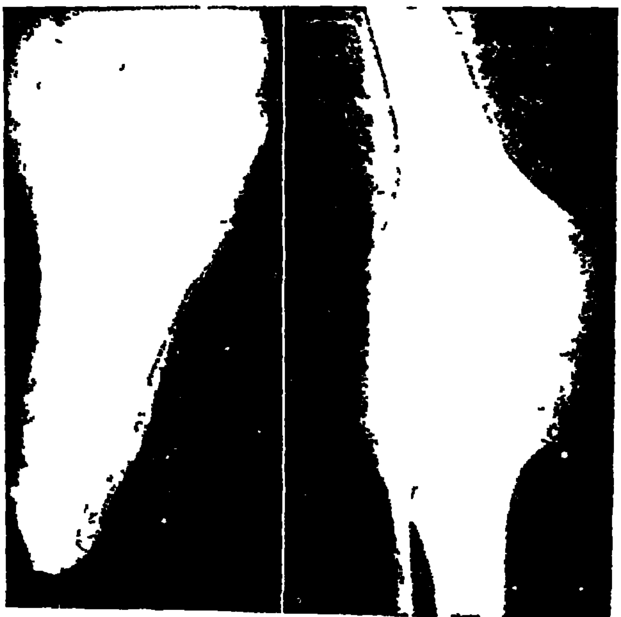

a   b

Fig 4—Radiographs of foot and knee. Note, *in the foot (a)*, the small size and the gross subluxation at mid tarsal joints and in the knee (*b*), the distribution of osteoporosis and Harris's lines

passive flexion was possible There was also 20° fixed adduction and internal rotation of the right hip, but almost full adduction and 20° abduction were possible in the left hip Both knees had flexion contractures, the right 50° and the left 40° Full passive flexion was possible The feet were both very small and were dislocated at the subtalar joint with 90° inversion The feet were 7½ in long and the tibiæ 6 in long—measurements similar to those of a child aged 6

Neurological examination revealed complete paraplegia at the *neurological level of* *T7, with no abnormality above this* level Below it there was complete loss of sensation to pinprick, posture, and vibration. Pinprick in the lower limbs produced a cross extensor response by which the patient knew that something was happening

The reflexes were normal in the arms, and the knee jerks were brisk and equal The ankle jerks and abdominal reflexes were absent, and the plantar responses doubtful There was a slow response in the sphincteric reflex

Obvious muscle wasting accompanied complete paralysis of all muscles below the level of sensory change The excellent function of his upper limbs, however, enabled him to move the matchstick lower limbs into a suitable position with a quick flick of the wrist and to move about with great agility

Investigations

Culture of the urine produced a heavy growth of *Streptococcus fæcalis* The blood-urea was 25 mg per 100 ml and the hæmoglobin 13 0 g per 100 ml

A plain X-ray film of the abdomen showed prostatic but no renal calculi Radiological features are illustrated in figs 2–4

Course

Bougies were passed, with some difficulty owing to a tight posterior stricture, and a Foley catheter left in for seven days A course of sulphafurazole (‘ Gantrisin ’) tablets was followed by aureomycin for five days

Further investigations were felt unjustifiable in a patient who was able to look after himself so satisfactorily After some difficulty on the first two or three occasions, he was able to re establish his catheterisation routine and was discharged home

Discussion

Among the unusual features of this case are

1 Survival despite inadequate treatment and a very poor prognosis

2 Absence of renal calculi or gross urinary infection despite many years' recumbency, and self catheterisation for twenty years

3 Paralytic dislocation of the right hip

4 Deformities and absence of growth of the lower limbs associated with paralysis and disuse

5 Rehabilitation to a self-supporting cheerful existence

Prognosis of the paraplegia—The complete flaccid paralysis, the sphincter disturbance, and the loss of vibration sense gave a poor prognosis for neurological recovery

Prognosis for life—The mortality-rate in various series of cases of Pott's paraplegia is given as 21% (Butler 1935, Seddon 1935), 25% (Dobson 1951), and 28% (Girdlestone 1940), in the series reported by Bosworth et al (1953) there were many advanced cases and the mortality-rate was over 60%

Urinary infection and stones—Guttman (1953) states that 22% of paraplegic patients develop renal calculi, and it is remarkable that our patient, during several years' recumbency, did not do so Occasional attacks of pain are probably due to mild recurrent urinary infection but up till his recent admission no long courses of antibiotics had been given That careful daily catheterisation can be so innocuous corroborates statements by Girdlestone and Somerville (1952) In this case no satisfactory automatic bladder was developed

Paralytic dislocation of the right hip—It seems likely that the dislocation of the right hip was a result of paraplegia Blundell Jones (1954) records such a dislocation in children with flaccid or spastic paraplegia It is usually accompanied by a valgus deformity of the femoral neck and is more common in children paralysed before the age of 2 It is attributed to lack of the moulding forces in the bone which are produced by normal muscle tone on weight-bearing

Deformities of the lower limbs are caused by osteoporosis, lack of growth, and muscle imbalance

Abramson and Kamberg (1949) attributed the bone changes to osteoporosis—i e, disturbance of the laying down of the bony matrix, rather than an alteration in the calcium deposition in bone, but they found that osteoporosis was commonly associated with soft tissue calcification and formation of renal stones These changes were largely prevented by ambulation within two years of injury Lack of growth is probably due to epiphyseal arrest, which is another result of long continued immobilisation (Gill 1944, Sissons 1952)

The feet also show changes resulting from osteoporosis, lack of growth, and muscle imbalance The adduction and inversion deformity is probably the result of prolonged invalid posture It causes little inconvenience since the legs are no longer used

Rehabilitation—Special hospitals have provided new hope for paraplegic patients This case illustrates how much can be done by simple determination alone, and provides many useful reflections for those confronted with such extreme disability

I should like to thank Mr W J Ferguson, M S, of the West Middlesex Hospital, for permission to publish this case, and Mr J I P James, M S, of the Royal National Orthopædic Hospital, for his helpful criticism

Medical Societies

ROYAL SOCIETY OF MEDICINE

Aortic Stenosis

A MEETING of the society's section of medicine on April 18, with Dr G E BEAUMONT in the chair, discussed aortic stenosis

Dealing with the medical aspects, Dr RAYMOND DALEY said there was a history of rheumatic fever in more than half his cases and a predominance of males Death occurred between one and two years after the onset of symptoms He emphasised the frequency of sudden death, presumably from ventricular fibrillation He thought that the finding of a thrill in the neck was much more important than that of a thrill in the aortic area The largest group of patients lay between the ages of 40 and 59 years, and of 23 patients in this group 18 had calcification of the aortic valve He had studied the brachial artery pressure pulse and while prolongation of the upstroke time was a good indication of aortic stenosis, there were many other factors to be taken into account such as the dynamics of the left ventricle and the characteristics of the recording system Using Mr Ian McMillan's system of taking cine photographs of the aortic valve, as well as other hæmodynamic data, they had come to the conclusion that the critical orifice size was 0 5 sq cm Dr Daley divided cases of aortic stenosis into four groups depending on severity In the first group the orifice was greater than 0 5 sq cm and there were no hæmodynamic effects In the second group the orifice was less than 0 5 sq cm , there were no symptoms, and there were no changes in hæmodynamics, except following effort, when the end diastolic pressure rose in the left ventricle In the third group there were symptoms, and in the fourth group there was failure of both left and right ventricles

Mr **Andrew Logan** discussed the surgical treatment of aortic stenosis He had performed an aortic valvulotomy, as he called it, in 31 cases In 7 he believed the condition was congenital, and in 17 acquired , in 7 the aortic stenosis was accompanied by mitral stenosis In 6 of the 7 congenital cases subaortic stenosis was thought to have been excluded by angiocardiography , in 5 of them aortic incompetence was produced or increased, but all had improved for the duration of the follow-up period (at least three years) In 1 patient there was gross dilatation of the heart in the immediate postoperative period, but it later returned to its preoperative size The indication for operation in this group had been evidence of extreme left ventricular hypertrophy on the electrocardiogram In the 7th patient unfortunately no angiocardiogram had been performed, subaortic stenosis was found at operation, and sudden death occurred five hours later In the 17 patients with acquired pure aortic stenosis the symptoms were such that none of them were expected to survive more than eighteen months without the aid of surgery 15 out of the 17 had calcified aortic valves, 9 had died, 4 in the immediate postoperative period or during the operation Of the 8 survivors all had some increase in aortic regurgitation, but 5 had improved from the symptomatic point of view and 1 had lost all symptoms although he had been in heart failure with angina before the operation Of the 7 patients with aortic stenosis and mitral stenosis there was improvement in all

Mr Logan said that he had been criticised as deducting a few months of life from one case of aortic stenosis to add it on to another by his surgical efforts, but he felt that the results in the surgery of aortic stenosis were not intolerable to any surgeon brought up on cancer In order to get better results he would like to operate earlier, but since the prognosis was uncertain until late it would be necessary at this stage to make a series of those with a pressure gradient across the aortic valve of, say, 50 mm Hg, and use alternate cases as controls Describing his technique Mr Logan said he incised the anterior wall of the left ventricle and introduced and opened a dilator in the aortic valve while the head vessels were clamped He thought this was better than the use of a sharp instrument because it tended to select the commissures more accurately He was impressed, however, with McMillan's work showing that if the aortic cusps were malformed valvotomy was useless He noted that ventricular fibrillation was common and that cardiac massage was difficult because of the great thickness of the left ventricular wall Immediate electric defibrillation was necessary He concluded by saying that he felt that blind dilatation of the aortic valve produced as good results as any operative technique yet devised, including open surgery under hypothermia

Dr **J F Goodwin** discussed work done with his colleagues at the Postgraduate Medical School, Dr Abdin, Dr Nielson, and Dr Doyle The cardiogram in severe aortic stenosis showed deeper T-wave inversion (due to myocardial ischæmia) than in hypertension and coarctation A deep s wave in lead V5 indicated additional right ventricular hypertrophy In severe stenosis the systolic upstroke time of the arterial pulse varied directly with the pulse pressure, but this was not true for mild stenosis or incompetence Measurement of systolic upstroke time in relation to the pulse pressure in a number of beats during the Valsalva manœuvre was a better guide to the severity of stenosis than examination of the resting pulse wave

Mr **W P Cleland** said he had performed an aortic valvotomy on 15 patients In 1 the ætiology was believed to be congenital, in 9 there was pure calcific aortic stenosis, and in 5 there was additional mitral stenosis 3 patients had died and in the remainder the longest follow-up period was three years All patients were in Dr Daley's third group, and he disagreed that they should have been in the second group He was fairly optimistic about the results; all the patients were holding their own The pressure gradients across the aortic valve varied between 50 and 150 mm Hg, and he was content with a 50% reduction in the gradient, since it was dangerous to go too far in these cases He thought that the trans-ventricular approach with a blind operation was satisfactory, but he hoped in the future to have a bloodless field and a still heart

Dr **Ronald Gibson** said that at the Brompton Hospital and at Guy's Hospital direct puncture of the left ventricle had been performed in 60 patients The procedure was simple and safe, but the systolic pressure gradient across the aortic valve obtained by this method must be interpreted with caution [1] The pressure gradient depended not only on the size of the orifice but also on the stroke volume, which was related to cardiac output heart-rate, and the degree of aortic regurgitation A gradient of up to 100 mm Hg had been found with dominant aortic regurgitation There was little correlation between the size of the pressure gradient for the ejection period and the surgeon's estimate of valve size This was due to differences in stroke volume There was a good correlation between the calculated aortic valve area and the prolongation of corrected arterial upstroke time with estimated valve size

Mr **Ian Hill** had operated on 2 patients with isolated aortic stenosis and 10 with aortic stenosis and mitral stenosis He had found it difficult to assess the severity of the aortic stenosis by manometry at operation because of the varying cardiac output, and he now passed a sound in order to assess the size of the orifice

Mr **D N Ross** said that Sir Russell Brock had now performed 100 aortic valvotomies using the transventricular approach [2] He agreed with Mr Cleland that one must not persist in trying to abolish the pressure gradient, because of the danger of ventricular fibrillation He did not know the exact mortality figures but they were about 10% They had used direct vision with hypothermia in about 15 cases of congenital aortic stenosis, and they had found a surprisingly high incidence of subaortic stenosis (11 cases out of 100) Calcification-of-valve stenosis was so common that if calcium was absent in a patient more than 30 years old, the stenosis was probably subvalvular, and this could be confirmed by taking withdrawal pressure tracings across the aortic valve on the operating-table Subaortic stenosis was treated by splitting from below, using the transventricular route

Mr **B B Milstein** noted the high mortality in the early cases and attributed it to their advanced nature (they were mainly in Dr Daley's group 4) He did not now operate on patients with heart failure unless this had been treated successfully for three months Angina and syncope were usually relieved by valvotomy, but dyspnœa often remained and was attributed to fibrotic changes in the myocardium

Dr **C J Gavey** emphasised the importance of the symptom of weakness in bad cases of aortic stenosis it usually indicated a poor prognosis

Mr **Ian McMillan** was asked about the varieties of abnormalities of the aortic valve as shown by his method of cinephotography he replied that fusion of one commissure producing the fish-mouth type of stenosis was the most common and had been found in 28 out of 47 cases

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE 58th *general meeting of the association* was held at Torquay on April 11

Radioactive Materials and the Pathologist

Introducing a symposium on this subject, Prof D H COLLINS (Sheffield) said that where possible the pathologist should collaborate with a team of medical scientists and physicists, but the use of isotopes would undoubtedly become wider and every pathologist should know about them To enable him to assess the risks the pathologist must be informed of the radiation history of every piece of potentially radioactive tissue, cadaver, or other biological material coming into his department The purpose of the symposium was to arouse the interest of clinical pathologists so that they might play their full and proper part in the coming era of radiation medicine

Discussing the injurious biological effects of radiation Dr R H MOLE (Harwell) said that interference with the processes of repair was a characteristic feature, and one basic problem was whether malignancy was a sequel to prolonged and inadequate repair or whether it was due to some sub microscopic cellular change such as "mutation" Another characteristic feature was the time required *for* biological damage to show itself The time scale was even more drawn out in man than in animals, so that the sperm count might be at a minimum six to ten months after a sublethal exposure A limited exposure to radiation in early adult life might shorten the life span In fact the sequels of low level irradiation might conveniently, if not very illuminatingly, be described as premature ageing Experience had shown that 1 µg of radium in the body might cause bone tumours Thus 0 1 µg was taken as the body burden which would not do harm—i e, the maximum permissible level (M.P L) for occupational exposure The M P L for other radioactive materials—e g, radioactive strontium—was based on this and took into account the amount of radiation energy absorbed in tissue, differences from radium in degree of uniformity of deposition, and metabolic differences in excretion and in uptake from food and water

Dr R C CURRAN (Sheffield) said that many of the radioactive isotopes in use in hospitals were given in trace doses, and though it was always wise to avoid all unnecessary radiation in view of the lack of knowledge of the effects on man of even a small increase over his "normal" radiation background, the hazard from handling these was comparatively slight Some isotopes, however, including ^{131}I, ^{198}Au, and ^{90}y, were given in far greater doses for therapeutic purposes When the pathologist was asked to examine a surgical specimen or perform a necropsy on a body containing such large quantities of radioactive material, it was essential for him to have all relevant information The hospital physicist should determine the residual radioactivity After dissection of a highly radioactive specimen, all appropriate areas of these departments should be monitored by the physicist, who would detect any persistent foci of radioactivity that must be eliminated

Control of the Hypothermic State

Dr P I REED (London) described investigations carried out in the department of neurosurgery of the Maida Vale Hospital on 31 patients undergoing craniotomy under hypothermia for vascular abnormalities The study was designed to demonstrate possible differences in biochemical findings compared with cardiac surgery, and to show what screening tests, if any, were of value in anticipating any of the recognised or theoretical complications of hypothermia Significant changes were found in the serum bicarbonate, blood sugar, and blood urea levels, the bicarbonate decreasing from 28 0 m eq per litre preoperatively to 24 2 at 27 5°C and 24 4 postoperatively, the blood sugar rose from 107 mg per 100 ml to 207 at 27 5°C and 148 postoperatively, and blood urea from 25 mg per 100 ml to 30 and 40 respectively Changes in sodium, potassium, calcium, chloride, prothrombin fibrinogen, coagulation time, and platelet count were not significant Neurosurgical patients were much less prone to acid base imbalance than those who had undergone cardiac surgery stimulating ventricular fibrillation, and they were less likely to develop liver damage and in consequence less prone to abnormal bleeding The following tests were therefore worth carrying out serum potassium and bicarbonate before and during hypothermia (as a guide to correcting acidosis) and blood sugar and urea (to exclude diabetes and early uremia respectively) Other tests were indicated only when complications, unassociated with hypothermia were suspected There was at present no way in which the laboratory could anticipate any danger due to hypothermia itself, apart from helping to exclude those patients in whom hypothermia was contra indicated

Tryptophan Metabolism in Phenylketonuria

Dr C M B PARE, Dr M SANDLER, and Dr R S STACEY (London) presented evidence of a defect in the 5 hydroxyindole pathway of tryptophan metabolism in phenylketonuric patients They showed that there was a significant decrease in serum 5 hydroxytryptamine (5 H T) levels and urinary excretion of 5 hydroxyindoleacetic acid compared with control groups Surprisingly high levels of serum 5 H T were found in some mentally defective children in the control group The low levels of circulating 5 H T might be related to mental deficiency in phenylketonurics, for certain evidence suggested that 5 H T was functionally important in the central nervous system The improvement in mental function in some phenylketonurics on a low phenylalanine diet might be related to the rise in circulating 5 H T which had been observed in a small number of patients undergoing this form of treatment A possible form of treatment was the administration of 5 hydroxytryptophan, which passes the blood brain barrier and is metabolised to 5 H T in the central nervous system As a working hypothesis to explain the 5 H T deficiency, it was suggested that the defect in hydroxylation of phenylalanine may affect hydroxylation of tryptophan, either by providing competition for a limited hydroxylating mechanism or by the inhibition of tryptophan hydroxylase by phenylalanine or one of its metabolites

Proteins of Normal Urine

In the technique of Grabar and Williams, proteins are first separated electrophoretically and then identified immunochemically by means of the precipitin reaction

Dr G H GRANT (Shrewsbury) had analysed in this way the urine proteins of a small number of normal men women, and children, using three rabbit antisera prepared against serum proteins, urinary tract proteins, and the Tamm Horsfall mucoprotein respectively Normal urine contained small quantities of a large variety of different proteins Many were electrophoretically and antigenically identical with the serum proteins The glomerular pores must be much larger than used to be supposed, but they were apparently not wide enough to let through the large β lipoprotein molecule There were probably at least 3 proteins in the urine unrelated to the serum proteins and so presumably arising from the urinary tract The principal one was the mucoprotein described by Tamm and Horsfall, which was precipitated from normal urine on increasing the concentration of NaCl The high proportion of "α globuline" found in normal urinary protein by moving boundary or paper electrophoresis was due *not to differential tubular reabsorption of* plasma proteins but to urinary-tract protein

Biochemical Treatment in Renal Failure

In the Glasgow Northern Hospital Group, in the past seven years, 12 obstetric cases out of 13 with acute renal failure have been successfully managed by conservative treatment Dr J W CHAMBERS (Glasgow) added that in the past three and a half years some 20 cases of uremia had been treated and had recovered, all had normal serum urea levels before discharge (except 2 with ureter transplanted to colon) Half these patients had acute renal failure, the others were mainly patients with renal insufficiency associated with severe electrolyte depletion or toxemia Maximum serum urea levels ranged from 100 to 500 mg per 100 ml Half the patients were semicomatose or confused, and a third had an episode of circulatory failure Treatment was guided by the principles and practice of Professor Bull, with special attention to rectification of electrolyte depletion as indicated by the history, clinical status, and biochemical findings In 75% of cases the prognosis at the outset was very bad 3 of the most severely ill patients were known to be well two and a half years later

Blood-loss Following Trauma

Dr ELIZABETH TOPLEY (*Birmingham*) said that comparison of different red cell volume techniques in parallel showed that equally accurate results were obtained using ^{51}Cr labelled patient s blood ^{51}Cr labelled bottled blood, and ^{32}P labelled patient's blood Comparison of clinical assessments of blood loss with red-cell volume studies had defined the common degree and timing of blood loss in a variety of injuries, and had demonstrated the limitations of clinical assessment Red-cell volume estimates in burns might be inaccurate if more than 20% of the body-surface was involved In spite of this, estimates six and twenty-four hours after injury had increased the usefulness of hourly hæmatocrits as a guide to plasma therapy during the shock stage in extensive burns Inspection of a blood-film taken on admission helped to decide whether red cell volume studies were necessary A loss of more than 25% of the normal red-cell volume had so far not occurred in patients showing less than 1% of microcytes (less than 3 µ) in the head of the blood-films

Complications After Valvotomy

Dr A **Dick** and Dr R **Mathieson** (Glasgow) discussed a series of 41 patients who were subjected to mitral valvotomy during the years 1952–56, 5 died within six months of operation Histological examination of the auricular appendages revealed evidence of rheumatic disease in all but of activity in only 1 of these 5 The necropsy findings indicated that 2 patients died of thrombotic lesions, 1 of cerebral emboli, and 2 of infection within three weeks of operation In 1 of the infective cases two varieties of penicillin-resistant coagulase positive staphylococci were isolated, one from the lung and pleural and pericardial cavities, and one from the blood This patient had profound toxæmia which failed to respond to antibiotics, and at necropsy there was a fibrinous pericarditis and pleurisy, but the classical features of acute infection were absent

Ulceration of the Œsophagus in the Newborn

Dr G R **Osborn** (Derby) said that ulceration of the œsophagus had not been observed in the embryo fœtus or in stillborn babies It was not a consequence of shock In babies born alive, ulceration was uncommon when they had not been intubated If intubation was intermittent or of short duration, little damage might be done to the œsophagus The incidence of ulceration in a nursing-home where intubation was often necessary was 12% when intubation was not undertaken to administer intragastric oxygen, 71% of babies treated with intragastric oxygen had ulceration of the œsophagus Intubation caused pressure atrophy of the epithelium progressing to total destruction Next, but very early, there was intense congestion, often associated with hæmorrhage into the muscularis mucosæ and main muscle coat Later, large bacterial masses might form on the eroded surface and the bacteria might invade the blood stream or become obvious in the gastric mucus Staphylococci were the most important

Venous Thrombosis and Bed Rest

Dr N M **Gibbs** (Derby) observed that venous thrombosis in hospital patients almost always involved the legs and it was decided to try to correlate the site and incidence of venous thrombosis in the legs at necropsy with the duration of bed rest in hospital The vessels of the legs were dissected in 239 cases in which the period of confinement to bed was accurately known 163 patients had died within two weeks of admission to hospital, and the duration of bed rest was assessed to within twenty four hours The incidence of venous thrombosis rose to a peak in patients dying after one to two weeks confinement to bed 76 patients died after from two to twelve weeks in bed, and the age of the thrombi corresponded to the duration of bed rest Venous stasis occurred in two distinct anatomical sites in the leg veins—the intramuscular veins, particularly those of the soleus muscle, and the common femoral vein and tributaries near the inguinal ligament Dr Gibbs concluded that the most important cause of venous thrombosis in the legs in hospital patients was venous stasis due to muscular inactivity Most fatal emboli arose from the common femoral vein and tributaries near the inguinal ligament Emboli detached from the legs were usually small and produced no symptoms

The Doubtful Lymph-node

Dr K R **Dempster** (London) said that lymph node biopsy sections from 102 patients, previously reported either as ' non specific chronic inflammation " or as doubtful ' in the sense that a malignant lymphoma could not be excluded had been re examined and the patients followed up 10 cases could be definitely diagnosed as malignant lymphoma (follicular lymphoma 3, Hodgkin s disease 4, lymphosarcoma 1, and reticulum cell sarcoma 2), unequivocal evidence of which was obtained by later biopsy splenectomy or necropsy Certain histological manifestations of chronic inflammation were particularly likely to cause confusion with malignant lymphoma Reactive follicular hyperplasia was often mistaken for follicular lymphoma but the uniform distribution of macrophages in the follicles and the presence of patent sinuses in the inflammatory condition were useful differential points Many microscopical features of Hodgkin's disease were mimicked by the multiple abscesses of cat-scratch disease and lympho-granuloma inguinale Sternberg-Reed cells were not found in inflamed glands and they indicated Hodgkin's disease

Carcinomatous Neuropathy

Dr A L **Woolf** (Smethwick) had studied intramuscular nerve endings by Coers s techniques in 2 cases of carcinoma In 1, there was collateral reinnervation of denervated muscle-fibres with diffusely swollen nerve-fibres "Strength-duration" curves indicated partial denervation of distal muscles of upper and lower limbs Necropsy showed a bronchial carcinoma with carcinomatous infiltration of cervical, lumbar, and sacral spinal roots between the arachnoidal cul de sac and the ganglion The cord (apart from wallerian degeneration from a metastasis in the pons), cauda equina, and dorsal-root ganglia were practically normal There were many necrotic cerebral metastases, one bordering on the ventricle The 2nd case presented as a predominantly sensory ' peripheral neuritis " Muscle biopsy showed collateral reinnervation, many slightly oval swellings with dark lilac central and paler outer zones (methylene blue) on the nerve fibres and reduction of some end plates to single approximately spherical masses An anaplastic carcinoma was found in the bifurcation lymph-node Plasma cells were mixed intimately with the tumour There was posterior-column degeneration and severe loss of nerve cells from the anterior horns. The medulla showed cellular nodules in the olives and other nuclei suggesting virus encephalitis, but further examination showed the nodules to consist of plasma cells developing Russell bodies and what were probably carcinoma cells The carcinoma cells appeared to have been surrounded by plasma cells from the tumour stroma, during their passage through the blood stream to the brain

---

Reviews of Books

The Eye in General Practice

C R S **Jackson**, B M, F.R C S E, ophthalmic surgeon, Royal Infirmary, Edinburgh Edinburgh and London E & S Livingstone 1957 Pp 152 21s

The talent to set out a complicated subject clearly and briefly is rare, but Dr Jackson has succeeded almost completely in his attempt to discuss in 152 pages the aspects of ophthalmology relevant to general practice Little of importance has been omitted and much matter, dear to ophthalmologists but of little concern to other doctors, has been left out

In a preface he says his intention is to describe the common diseases of the eye, to show how to distinguish conditions which need hospital attention from those which can be safely treated by the family doctor, and to help the practitioner to interpret letters from a hospital eye clinic and be able to reassure his patients These aims have been well fulfilled

The book has three main sections In the first part, devoted to the diseases of the eye, an introductory account of examination is followed by chapters on each of the structures liable to disease and separate chapters on refractive error, squint, and glaucoma That on squint (a subject about which there is too much complacency) is of special merit Squint is not only a cosmetic problem which causes much needless emotional hardship to school children but also the commonest cause of the ' *lazy* " *eye—that* is, an eye which has usually lost all useful central visual acuity Dr Jackson emphasises how poor are the results when treatment is delayed and how good when it is early

Part II is devoted to ocular manifestations of cardiovascular endocrine, and metabolic diseases, and diseases of the brain, ear, nose, throat and skin Part III has two informative chapters on subjects about which there is much ignorance—the welfare of the blind and the ophthalmic side of the National Health Service

There is no section which sums up the indications for local cortisone in the eye Though very useful in many eye conditions, cortisone is potentially dangerous in the presence of infection, but this is not clearly stated Not all ophthalmologists will agree that cortisone is justified in the treatment of disciform keratitis, a virus infection of the cornea which, though usually self limiting, has no specific treatment Most of the coloured illustrations are good, but some could be improved by magnifying the view of the eye and eliminating the surrounding face

Though intended for general practitioners, the book should be more widely used Augmented by clinical teaching, it will provide almost all the medical student needs to know, and many consultants will find it useful as a basis for lectures to nurses

The Physician-Writer's Book

Tricks of the Trade of Medical Writing Richard M Hewitt, A M, M D, senior consultant, section of publications, Mayo Clinic, associate professor of medical literature, Mayo Foundation, Graduate School, University of Minnesota Philadelphia and London W B Saunders 1957 Pp 415 63*s*

Guide to Medical Writing

A Practical Manual for Physicians, Dentists, Nurses, Pharmacists Henry A Davidson, M D, editor, *Journal of the Medical Society of New Jersey* New York The Ronald Press Company 1957 Pp 338 $5 00

For books on medical writing we are largely dependent on America Fishbein's classic, *Medical Writing*, was followed a few years ago by the delightful work of Jordan and Shepard, ℞ *for Medical Writing* Our debt to America is now increased by two more works, as different as chalk and cheese, and each more comprehensive than the two earlier books

Dr Hewitt is a pupil of Fishbein and has spent all his life as a professional full-time editor He is soaked in Latin, Greek, and English, and his many references include Demetrius, Horace, Pascal, Boswell, and Hazlitt, this scholarly background explains his dominant interest in English composition and style

The book itself falls into seven parts the whole article or book, the paragraph, the sentence, words, tables and illustrations, preparation of manuscripts, and the ethics of writing The text is amplified and illustrated by 21 appendices, but the material in the appendices could readily have been incorporated in the text

The author's style is discursive and conversational and suggests tape recordings of his seminars His approach to any topic is oblique and full of personal reminiscence, so that it is far from easy to see what he is driving at The book has an unusually full table of contents and a good index

Dr Hewitt's vast experience would have made a more effective book if it had been brought into sharper focus

Dr Davidson—a practising psychiatrist—is a born journalist and his book a superb piece of concise exposition He is everywhere crystal-clear and he never wastes a word, though the style is sometimes slangy The reader is instructed in how to start and organise articles, select catchy titles, hook " reader-interest," and master the tactics of syntax Other sections deal with the treatment of names, numbers, and nomenclature, case-histories, and the writing of summaries and conclusions The most original chapter is *The View from Olympus*, which discloses one way in which editorials are conceived and written

Physiologie und Pathologie des Lymphkreislaufes

Prof István Rusznyák, Mihály Földi, dr med, György Szabó, dr med, I Medizinische Universitäts Klinik, Budapest Budapest Verlag der Ungarischen Akademie der Wissenschaften 1957 *Pp* 836

The pathology of the lymphatic circulation is a neglected subject Many points were elucidated by the work of Drinker and his associates, and this work was summarised in 1941 in Drinker and Yoffey's monograph Succeeding work has been scattered in a variety of journals, but Professor Rusznyak and his colleagues have now drawn it together admirably

After a historical introduction the book describes in detail the anatomy and physiology of lymphatics, with particular emphasis on œdema formation The work done since Starling's day is thoroughly reviewed, including the authors' own investigations and Eppinger's studies on capillary permeability Attention is directed to the importance of Haitinger's fluorochrome method in the study of capillary permeability in pathological conditions and under the influence of various drugs A few sections stained by this method are reproduced in colour photomicrography Finally, the authors discuss the lymphatic circulation and its pathological changes in individual organs There are about 2000 references, some in Hungarian or Russian and not easily accessible The paper, print, and illustrations are excellent

Both the publishers, the Hungarian Academy of Sciences, and Professor Rusznyák and his colleagues are to be congratulated on this addition to medical literature

Liver Structure and Function

Hans Popper, M D, PH D, professor of pathology, Northwestern University Medical School, Chicago, Fenton Schaffner M S, M D, co chairman, Dept of Medicine, Woodlawn Hospital, Chicago New York, Toronto, and London McGraw Hill 1957 Pp 777 $20 00

No doubt it is the new knowledge derived from experimental studies and the widespread use of aspiration biopsy that has led to the steady crop of books on the liver and its diseases The combination of functional and structural investigation has now reached the stage when the two can profitably be correlated in both the healthy and the diseased organ, and this attempt by Professor Popper and Dr Schaffner is extremely successful They have not only achieved their primary objective of correlation, but they have also produced an excellent textbook Its encyclopædic content and the omission of anything about treatment may make it unsuitable for the student reading for higher qualifications, but it will undoubtedly be the standard reference book of its subject for years to come The bibliography contains 3735 references and is supplemented by an appendix, a sort of " stop-press " news bringing each chapter up to date about six months before publication—a remarkable feat The publication and the lavish illustrations are of high quality

The senior author, a student of Eppinger, has shared in producing a worthy successor to Eppinger's famous book As the authors claim, it is " a complete source book on the liver in health and disease "

The Management of Abdominal Operations (2 vols 2nd ed London H K Lewis 1957 Pp 1326 160*s*)—With one exception the contributors to Mr Rodney Maingot's book are the same as in the first edition its character therefore remains unaltered, though its form has been improved by substituting two volumes for the original one, whose bulk sat uneasily in the lap Revision has been undertaken, and almost all sections are fully up to date But it is a pity that no mention is made in the chapter on chemotherapy and antibiotics of the dangers arising from the encouragement of insensitive staphylococci, though the subject is referred to briefly under complications of the wound The special value of erythromycin receives no more than a line under peritonitis, and pseudo membranous enterocolitis is listed under complications of gastric operations, but is not discussed Since the book is concerned essentially with management, operative technique could with advantage be excluded from certain chapters For the postgraduate surgical student, this book will remain a valued guide

The Neurohypophysis (London Butterworth's Scientific Publications 1957 Pp 275 30*s*)—The proceedings of the symposium on this subject held by the Colston Research Society in Bristol last year have been published under the editorship of Prof H Heller

Microbial Ecology (London Cambridge University Press 1957 Pp 388 32*s* 6*d*)—The 7th symposium of the Society for General Microbiology was held last month and microbiologists from Britain and the United States took part The papers, which are edited by Dr R E O Williams and Dr C C Spicer, chiefly discuss the relationships of micro organisms with their inanimate environment, with each other, and with higher forms

THE LANCET

LONDON SATURDAY, MAY 11, 1957

Relatives in Hospital

It may puzzle a future generation of doctors that the medical students of today, though encouraged to spend many an idle minute gossiping with their patients, often qualify without having listened to a devoted wife being told that her husband will be dead before next Christmas, without having seen new hope kindled in the eyes of a sick child's mother, and without having been startled as the cause of a perplexing intestinal disorder is laid bare in the natter of a nagging wife or the bluster of a tyrannical husband. Nor are they usually taught—and many never learn to appreciate—the profound effect visitors have on sick people in hospital. Most of them take infinite pains to spare their patients physical hardship and mental anguish; but between three and four in the afternoon any well-meaning friend can talk the convalescent case of coronary thrombosis into a heart-attack, and milk-drips can beat solemn time to tales of unrelieved gloom. But if the protective isolation of a hospital should give the housewife her first chance in years to sleep undisturbed, to eat well, and to talk in complete sentences, to the proud mother regular visitors with the family news are as vital as rest, good food, and shots of the latest wonder-drug; and to the gravely ill the quiet presence of a husband or mother, just sitting close to the bed, passing a drink or (in answer to a familiar flicker of the eyelid) adjusting a crumpled pillow, brings comfort and solace that the best nursing care can never replace. In his contribution to a well-conceived group of articles on this subject in the *University of Leeds Medical Journal*, HELLIER writes: "The psychological effect of a relative's visit will obviously depend on circumstances; and these should be carefully considered before encouraging or discouraging visitors. . . . A regular visitor who can bring a needle and cotton or a favourite bottle of eau-de-cologne gives the patient a feeling that she has access still to her possessions."[1]

Patients at either extreme of life offer a special challenge to doctors, nurses, and hospital administrators. Children require strong emotional support in an emergency; and HELLIER is in no doubt that against emotional stress "the mother is the most effective prophylactic." Like ILLINGWORTH and HOLT,[2] whose pioneering inquiry we published in 1955, he believes that the initial disturbance of daily visits soon passes off and that only such close contact can prevent "the psychological scars of prolonged hospitalisation in childhood" which he sees in many adults today. At St James's Hospital in Leeds accommodation is provided for mothers to be admitted with their ill children—a striking contrast to venerable institutions which still allow their visitors to queue up in the rain. At the other extreme of life fear from our hostile world torments no longer; it is the long-legged shadows of the next which begin to assemble around the bed. Some elderly sick take to solitude with calm serenity—it becomes to them the audience chamber of God—but to the majority it is hell let loose on earth. Relief from their agony calls for patient inquiry from nurse, almoner, and social worker (for there is often some trivial obstacle in the way of visiting), but the ultimate responsibility for their peace of mind rests with the doctor. Only he can impress on the reluctant relatives of a dying man that, however strained and perfunctory their visit may seem to them, it is that magical coin which he most desperately needs—just as the doctor alone can tactfully relieve a relative from the moral compulsion of sitting up night after night by the bedside of an unconscious patient in extremis.

On the mentally ill, even more than on children and the old, outside visits may have a dramatic effect. Recalling our earlier appeal for easier access to mental hospitals,[3] Professor MACCALMAN, in a posthumously published article,[4] reminds us that "we are all members of a group—the family—and small though it is, it provides a nucleus of security for which there is no substitute." Yet, at the critical moment when the patient "finds himself suddenly, and perhaps violently, uprooted from everyday life, and cast into the confusion and indignity of a mental-hospital ward—there to wage unequal combat with the unspoken suggestion that he has done something he ought not to have done,"[5] he is both spiritually and geographically isolated from this source of strength.

If scant attention is being paid to the effect of visitors on hospital patients, most doctors feel that the effect patients may have on their visitors hardly concerns them at all. Nothing can be more comforting to a child coming round from an anæsthetic (and more trouble-saving to the nursing staff) than the mother's smile; but mothers deserve a warning before being confronted with an unconscious child smeared with blood and vomit. Seriously ill patients can be so changed in appearance that relatives, seeing them thus for the first time, may be unnecessarily alarmed; and their alarm will often communicate itself to the patient. And children should not be allowed to see adults gravely ill—or even Granny's familiar face without her false teeth—except for some special reason. The difficulty of obtaining accurate information from hospitals still causes much animated correspondence in the lay press; and doctors who dismiss this as yet another unpleasant manifestation of the *Zeitgeist* should occasionally visit sick friends incognito. There is no doubt that parents are still being fed on junior nurses' garbled versions of their child's major illness; and few are the happy doctors who have not been summoned to family conclaves where worried relatives try to piece together dropped hints from sister-in a-hurry, conversational fragments from patients-in-the-know, and ambiguous statements from popular health manuals. The reason for this secretiveness is neither pressure of routine work, nor delight in conspiratorial hocus-pocus nor the callousness of youth. To interview relatives is a subtle and exacting art (far more complicated than interviewing patients) which should be taught to every medical student as assiduously as the examination of the chest. But because the young doctor has received no such education, he is oppressed by the fear that under the anxious scrutiny of relatives he will make a fool of himself. And in fact, when indignantly (for there is usually some more pressing and congenial task to hand) he faces his ordeal, his performance is thoroughly lamentable. It is difficult to decide which is worse—the cocky "just-leave-it-to-us-and-don't-you-worry" attitude of some, or the nervous diffidence of others—and hilarious stories about relatives overheard mispronouncing medical jargon cast a poor light on their learned source of origin. The losers in this cruel game are, of course, the doctors even more than the relatives. The wise clinician not only talks to the family, but also makes them talk to him, and he takes careful note of tell-tale gaps as well as of the tale they tell. All relatives when first seen are upset, and, not being under the special licence of the sick to unburden their souls without restraint, their conversation becomes a mixture of wishful thinking, morbid fantasy, and time-honoured euphemisms. "Many mothers . . . bringing children suffering from an obvious behaviour disorder are eager to tell us about the time when he fell out of the pram as an infant, and relatives of those with psychosomatic disorder descant about his physical infirmities to the exclusion of all else."[4] But misinterpretations can be as revealing as hard facts, and even the silences of the strong silent father or the meek masochistic mother can point to the need for treating the relatives as well as the patient. "This more than doubles our task, but without it all our efforts to *help the patient may be in vain*."[4] With predominantly hereditary or familial disorders the value of examining all members of the family is obvious, but careful inquiry into the family history may be equally important when patients are genetically predisposed to a disease but not yet affected by it, when, in fact, careful adjustment of their environment may still prevent its onset. It has recently been claimed that, not only do the children of diabetics run an increased risk of developing diabetes, but, before they do so, many show small reversible blood-vessel changes, and treatment of these might possibly prevent the diabetes. CARTER[6] believes that "this type of preventive approach will become increasingly important for many of the now common disorders."

[3] *Ibid*, 1956, i, 334.

[4] MacCalman, D. R. *Univ. Leeds med. J.* 1957, 6, 1.

[5] Woodley, H. G. *Lancet*, 1956, i, 338.

That relatives have a legal right to see the doctor during their visit to hospital is now accepted. (HELLIER[1] mentions a case where a relative slipped and broke a leg while trying to locate a house-physician, and for this accident the hospital was held responsible.) But surely from a humane profession they have a moral right to expect more than this. We should appreciate the immense nervous strain, and often the financial burden, that hospital visiting can entail, and hospital management committees, which justly pride themselves on providing all comfort for their patients, should look after visitors with equal consideration. Their difficulties may be great—they range from deterring visitors from collecting expensive souvenirs to providing lavatories—but these must be overcome. The good name of a hospital depends today—and it will depend even more in the future—on its cooperation with the families and friends of the sick as well as on its care of patients. These twin tasks are indeed already inseparable.

Wilson's Disease

IN the past decade much has been learnt about Wilson's disease (hepatolenticular degeneration). There can now be no doubt that disordered copper metabolism is the underlying cause. Urinary excretion of copper is increased[1] and the copper content of the brain and liver is also enhanced[2], but the serum-copper level is low.[3,4] The association of high tissue-copper levels with high urinary excretion of the metal suggested that too much copper may be absorbed from the alimentary canal, and that this is so was proved by ZIMDAHL et al.[5] who in careful balance studies showed that in a three day period healthy subjects retained 79–140 µg. of copper, whereas patients with *Wilson's disease retained* 1·6–1·8 mg. Possibly this excessive retention is due to failure of some mechanism in the alimentary mucosa which normally inhibits absorption of copper. (An alternative interpretation—that copper absorbed from the alimentary canal is not excreted, as it normally is, into the bile—seems to be excluded by the finding of approximately normal *levels of* biliary copper.)

Like most metals copper has an affinity for proteins, the positively charged metallic ions forming a loose complex with the negatively charged parts of the protein molecule. It might be expected *therefore* that copper would exist in serum in such a combination, but plasma-copper has been found to exist mostly as a much more firmly bound complex. This was isolated by HOLMBERG and LAURELL,[6] who named it cæruloplasmin because of its blue colour. SCHEINBERG and GITLIN[3] *found that* in patients with Wilson's disease the serum level of cæruloplasmin was much lower than in health. The slight reduction in serum-copper found by these workers bore no comparison with the almost complete absence of cæruloplasmin, and it was clear that the serum must contain much copper in an abnormal *form*. Studies with radioactive copper led to a similar conclusion. EARL et al.[7] showed that radioactive copper (^{64}Cu) given by mouth to healthy people is at first attached to the albumin fraction of the serum-protein as separated by ammonium sulphate, and the same is true of ^{64}Cu added to serum in vitro. But samples of blood taken twenty-four hours after administration of the copper showed that this had been transferred from the albumin to the globulin fraction, and presumably in the interval the ^{64}Cu had been incorporated into the cæruloplasmin molecule.

On the other hand, in Wilson s disease this transfer of copper from albumin to globulin does not take place the radioactive copper remains associated with the albumin fraction These findings accord with the observation by **Scheinberg** and **Gitlin** that in this disease the plasma level of cæruloplasmin is low It seems that the low level is due to defective synthesis in the body, which leads to the presence in the serum of large amounts of copper bound to protein but not so firmly as it is in the cæruloplasmin molecule , and is presumably this copper which is deposited in the brain and liver and results in the clinical manifestations of the disease Why the copper is deposited in the brain and particularly in the basal ganglia is uncertain, but normally basal ganglia contain a large amount of copper and possibly there is a protein there with a high affinity for the metal **Porter** and **Folch**[8] examined the form in which copper is laid down in the brain and have found notable differences between healthy subjects and patients with hepatolenticular degeneration **Chalmers** et al[9] have now put forward the hypothesis backed by some experimental observations, that liver-protein from patients with this disease has a greater affinity for copper than has protein from normal liver They feel that the excessive deposition of copper may be related to this rather than to the abnormal circulating copper

Treatment of the condition with dimercaprol (**Bal**) was first reported in 1951[2,10] This drug forms a stable non-toxic complex with copper and causes it to be excreted in the urine in even larger amounts In some cases this drug improves the clinical state—which strengthens the supposition that excessive deposition of copper is the immediate cause of the disease Lately other methods of treatment have been used Oral administration of potassium sulphide regularly with meals diminishes the alimentary absorption of copper by forming insoluble copper sulphide **Walshe**[11] has found that penicillamine increases the excretion of copper Calcium disodium ethylenediamine tetra-acetate has also been used, but has the disadvantage that it must be given intravenously

The diagnosis of Wilson's disease by chemical methods depends on demonstrating excessive copper in the urine or a low serum level of cæruloplasmin Small amounts of copper are not easily estimated, and there is always a possibility of error from contamination of the specimen with extraneous copper For this reason the estimation of cæruloplasmin, particularly by the simplified method of **Ravin**,[12] is probably to be preferred Serum-cæruloplasmin can be estimated indirectly by measuring the rate of oxidation of paraphenylene diamine in the presence of the serum , the rate of oxidation is proportional to the level of cæruloplasmin From **Denny-Brown**'s work it is apparent that the success of treatment with dimercaprol depends a good deal on early diagnosis Clinically the diagnosis in the early stages may be extremely difficult or impossible , so such helpful chemical methods are highly important

Long-term Studies in Man

Atheroma is perhaps the most important unsolved problem in human pathology and certainly the most discussed In the welter of observations and speculations on the relation between coronary-artery disease and dietary fat, three facts now stand out beyond dispute First, coronary artery disease is closely associated with a disturbance of blood lipids and in particular with high levels of cholesterol in the serum Secondly, in countries and communities with a high prevalence of coronary-artery disease, the susceptible population have levels of serum cholesterol and intakes of dietary fat higher than are found in countries where the disease is less common (In these epidemiological studies **Ancel Keys** and his colleagues at the University of Minnesota have been pioneers) Thirdly, in people whose level of serum cholesterol is high it can be lowered by altering the quality of the fat in the diet The study of the effects of different dietary fats on serum-cholesterol levels which Dr **Ahrens** and his colleagues present at the front of this issue confirms and amplifies earlier reports from themselves and others The most sceptical critic cannot now dispute the fact that the quality of the dietary fat influences the levels of serum-lipids He must be strongly impressed, too, by the evidence that the ability of the fat to lower the level of serum-cholesterol is associated with its degree of unsaturation, though, as **Ahrens** points out, other chemical properties of the fat have not been completely ruled out. Of course other factors besides diet—e g , the constitutional make-up of the individual, hormonal activity, and perhaps the extent of physical activity—also determine in part the levels of serum lipids Nor is it satisfactorily established that patients are clinically improved, and the risk of cardiac infarction reduced, when the serum-lipids are held continuously at low levels by a dietary regime All this obviously needs further study Unfortunately few medical centres in the world have, as yet, the organisation necessary for experiments on man on the [illegible] required

Mankind owes a great debt to laboratory [illegible] and much help has been obtained from the [illegible] acquiring an understanding of the nature of [illegible] arising as a result of acute infections and [illegible] deficiencies But, whereas there is much patho[illegible] common between a guineapig and a man [illegible] from generalised tuberculosis, and also be[illegible] rabbit and a child blinded by keratomala[illegible] animal counterparts of the [illegible] diseases of man either do not exist, [illegible] to human disease Hence it is [illegible] examine the progress of diseas[illegible] mentally controlled conditio[illegible] colleagues say that "the un[illegible] studies "was based on the [illegible] experiments can be carried o[illegible] as in animals" In this belief [illegible] the fortitude of the 37 citizens [illegible] prepared to live for periods ra[illegible] months without eating any na[illegible] entirely on synthetic diets [illegible] able to do so and for the [illegible] improve in health on these a[illegible] tribute to the skill and sym[illegible]

Rockefeller Institute and also to the administrative arrangements.

Advancement of our understanding of several important pathological processes would be much accelerated by the study of patients under similarly controlled conditions for periods to be measured in months. But although some teaching hospitals in Britain have small metabolic wards, none are provided with the staff or equipment required for studies on such a scale over so long a time. To ensure both the physical and social well-being of experimental patients and the accurate collection and analyses of data a very large staff is needed, as well as floor space for laboratories and social amenities: to care for and investigate thoroughly 5 patients, a staff of 25 to 50 persons may be necessary. But the setting up of one or more such research centres in this country would have immense practical value. Properly safeguarded, *Homo sapiens* can be a very useful laboratory animal.

RACIAL DISCRIMINATION IN MEDICINE

THE Natal Provincial Administration, noting that the salary scales in their hospitals have always distinguished between nurses and teachers of different races, decided recently to extend this principle to the eight non-European doctors working as interns at Edendale Hospital, Pietermaritzburg. These doctors have resigned in protest.

Since 1950 in South Africa graduates in medicine have had to hold house appointments for a year in an approved hospital before registering with the South African Medical and Dental Council. In 1950, though no Transvaal provincial hospitals would employ non-European doctors, the number of non-European medical graduates from Johannesburg was small enough for all to find posts in mission hospitals or in the British Protectorates. In July, 1951, however, three Indian graduates could not find a place; and apparently no one was responsible for finding them one. For several months they searched in vain for appointments; and it was not until their plight had been given publicity by various student and professional bodies that arrangements were made for them in a provincial hospital serving non-Europeans. The practical difficulty that had to be overcome was that white nursing sisters in South Africa could not be expected to "take orders" from non-white interns. (The seriousness of this difficulty is emphasised by the provision of the present Nursing Bill, which imposes a fine of up to £200 on anyone allowing a white nurse to work under a non-white person.) This obstacle was circumvented in the Transvaal provincial hospital by employing non-white sisters in units where non-white interns were placed. Like all other Transvaal provincial employees, however, these interns in Transvaal hospitals were paid at a lower rate because of their race—a state of affairs accepted by the profession, no doubt because of the urgent need to enable them to serve their statutory year. At that time the Natal Provincial Administration was not prepared to give appointments to non-European interns in any of its hospitals: even the 1500-bed non-European hospital in Durban did not have non-European interns, though its present connection with the medical school for non-Europeans has obviously changed the position. Influenced probably by a serious shortage of junior doctors, it later decided to appoint non-European interns at Edendale Hospital; and these are the appointments now made vacant by resignation.

In South African society, different rates of pay for European and non-European doctors will be regarded by many as logical and consistent. It is entrenched national policy in industry and agriculture, and in other professions such as nursing and teaching (although not in university lecturing). To the South African doctor, however, it does raise a new issue, since differential rates affect not only the economic but inevitably the professional status of all his colleagues. The events of recent years are a challenge to the standing of the South African medical profession of which it is well aware. The British Medical Association's cancellation of its proposed conference in South Africa, because satisfactory arrangements could not be made for all delegates regardless of race, was a grave blow. When the South African government decided that only white donors might give blood to white recipients and that blood bottles were to be labelled accordingly, many South African doctors felt this as a slur on the scientific reputation of their country—though the Medical Council thought it could not act in this "political" issue. The recent decision to impose apartheid in all universities and medical schools is considered a threat to the maintenance of equal professional standards for all graduates. Different status and different training for non-European nurses, now to be added to the already existing lower salary scales, will also have repercussions for the medical profession. Not long ago a South African local authority advertised in the *South African Medical Journal* for 15 "European" general practitioners to attend to its employees. The local branch of the Medical Association have published their emphatic opposition to the racial discrimination implied in the advertisement and have approached the authority with a view to its revision. They recognise the duty to resist discrimination against colleagues.

At its March meeting the South African Medical and Dental Council decided after debate that non-European interns, in accepting posts at different pay-rates from European interns, did not contravene its ethical rules. The executive regarded the matter of differential rates as one of public policy in which it was inappropriate to intervene. On the other hand, many members of the profession hold that, though the rules of the South African Medical and Dental Council may not have been contravened, such discrimination does not conform with Hippocratic ethics. The professional interests of South African doctors are threatened in many ways by this and the other developments in the medical schools and the nursing profession. Consistent ethical and professional standards, scientific freedom, and a ready exchange between nations are essential to the advance of modern medicine in all countries.

NEPHRITOGENIC STREPTOCOCCI

ALTHOUGH Bright[1] observed over a hundred years ago that renal disease with albuminuria may follow scarlatina, the significance of hæmolytic streptococcal infections in the pathogenesis of acute glomerulonephritis has been slow to emerge. Nowadays it is believed that infection with group A streptococci may result in at least two non-suppurative complications—rheumatic fever and acute nephritis—but while the link with rheumatic sequelæ is well substantiated, until recently the evidence for the link with glomerulonephritis has been patchy. Much of the earlier work establishing the streptococcal association of acute rheumatism was epidemiological, but with glomerulonephritis epidemiology reveals no discernible pattern. In patients with scarlet fever (when this disease was very common) the incidence of nephritis varied very widely,[2] both between epidemics and from year to year. Rammelkamp and his colleagues,[3] using

[2] Hansborg H *Acta med scand* 1925 61 576

[3] Rammelkamp, C H Weaver R S Dingle J H *Trans Ass Amer Phycns* 1952 65, 168

Lancefield's precipitin method of typing group A streptococci to study the distribution of streptococcal types in nephritis, showed that among sporadic cases in Cleveland, Ohio, the majority were associated with type-12 infections, and some with type 4. This preponderance of type 12 among strains inducing acute nephritis has been confirmed by independent studies, including a small British series.[4]

Rammelkamp[5] now affirms that there is strong evidence of specifically "nephritogenic" strains of group-A streptococci; these commonly belong to type 12, to type 4, or to a new type—Red Lake—recently identified by Updyke et al[6] in an epidemic of scarlet fever and nephritis in an Indian reservation in Minnesota. There is evidence, too, that children who have recovered from acute glomerulonephritis usually exhibit type antibody to one of the nephritogenic types of streptococcus.[7] There is a strong contrast here with rheumatic fever, in which no particular types or strains of group A streptococci have been incriminated as "rheumatogenic," although such evidence has been much sought. (In the Red Lake outbreak the source of the preponderant type was often in skin lesions. Does rheumatic fever ever complicate streptococcal infections unless they involve the upper respiratory tract?)

A striking point in Rammelkamp's work is that many strains of streptococci of types 12, 4, and 25 (another occasionally nephritogenic type) undergo lysis after infection with a bacteriophage not usually lytic for other serological types. It is known[8] that bacteriophage may convert avirulent diphtheria bacilli to toxigenic mutants; and possibly, as Rammelkamp suggests, a similar phenomenon determines the pathogenesis of nephritis. But it is necessary to bear in mind Maxted's work[9] on streptococcal phages, which showed that the hyaluronic acid capsule of certain mucoid strains protects against phage action; and it should be noted that Rammelkamp's type 12 strains are described as non-mucoid. Further studies on lysis of these strains will be of great interest. What has been discovered so far seems to indicate that in the causation of acute glomerulonephritis the peculiarity lies largely in the organism: in rheumatic fever it may lie in the host.

DEVELOPMENTS IN CANADA

After thirty years' consideration, Canada has taken the first step towards a national health service with a hospital care insurance plan which is to come into action early in 1959. Six out of ten provinces, containing more than half the country's population, have signed agreements with the Dominion government to set up hospital insurance systems to be financed jointly by the Dominion and provincial governments. With six provinces participating, the cost to the Dominion will be $100 million a year, a sum expected to be doubled when all ten provinces join in. The proposed plan includes standard ward care in general hospitals, with some diagnostic service and treatment, and care for the chronically ill. Benefits will be unlimited and cover universal; but treatment in tuberculosis sanatoria and mental hospitals will be excluded.

At present, 9 million people—about two thirds of the population—have some form of pre-paid hospital insurance from a wide variety of sources. Two provinces (British Columbia and Saskatchewan) have a universal compulsory insurance system financed by premiums and sales taxes, while two others (Alberta and Newfoundland) have voluntary plans for certain areas. Five plans for pre-paid care, sponsored by hospital associations, give service benefits to participants, and many commercial insurance companies are also in the field, offering set cash indemnities against sickness and accident. But the non-governmental agencies provide only limited benefits; and, since their cover is directed mainly towards groups of employees, the rural population and the self-employed can gain protection only through the high premiums set for individuals.

Cover for medical and surgical care is even more diversified than for hospital care and much less adequate. Some provinces provide for the treatment of specific diseases, such as tuberculosis, cancer, poliomyelitis, venereal disease, and mental illness, free or on a means test, and some provide free medical care for pensioners and people receiving public assistance. On the prairies and in the maritimes, a number of municipalities have salaried community doctors, and a few industries have company doctors. Commercial companies also insure against medical costs. A million and a half people are enrolled in eight plans for prepaid medical care sponsored by doctors' associations as an alternative to State medicine. These latter plans are the most popular and give the most comprehensive benefits; but, like the plans operated by hospital associations, their cover is so far confined to groups of employees.

Since hospital expenses are usually the heaviest part of medical costs to the patient, the new hospital care insurance plan meets the strong demand for some provision against the risks of illness—and meets it in a politically safe area. The Dominion government has firmly stated that it will not control or interfere with the hospitals. Doctors, though opposed to any State plan for complete medical care, have generally approved pre-paid hospital care where it has been tried. The introduction of a comprehensive medical service is not, of course, prevented only by resistance from professional bodies. Under Canada's federal constitution, matters of health and welfare are a provincial responsibility; and, even with the Dominion government footing half the bill, the poorer provinces could not assume the tax burden of a complete health service.

THE HOSPITAL BED

Efficient use of hospital resources was never more necessary; and the means to this end were helpfully discussed by the Institute of Hospital Administrators[1] at Torquay last week. Dr G. E. Godber, deputy chief medical officer of the Ministry of Health, began by saying that, on the medical side, we must be sure that treatment really does require the use of a bed and cannot be undertaken satisfactorily by the family doctor or in the outpatient department. Once admitted, the patient's medical needs require that his stay in the bed should be for the shortest period compatible with adequate treatment, and he should never be kept in the hospital for investigations or forms of treatment which could equally well be carried out while he is living at home. Though the doctor and nurse are concerned with doing their best for the patient actually in the bed, some account must be taken of the queue of other patients, behind his shoulder, whose need may be no less great: at the end of 1955, for every bed allocated to general surgery there were nearly four patients awaiting admission, and in gynæcology and ophthalmology there were six. Though nobody should be hustled out of the hospital bed to his own disadvantage, the waiting-list is a valid reason for taking special care that no time is lost in returning a patient to his own home if treatment can be completed there. Commenting on the fallacies of "bed occupancy" as an index of efficiency, Dr Godber pointed out that

PUBLIC REACTION TO THE CURRENT DISPUTE BETWEEN THE MEDICAL PROFESSION AND THE GOVERNMENT *

J H F BROTHERSTON
M D Edin , M R C P E , D P H

ANN CARTWRIGHT
B Sc Lond

F M MARTIN
B Sc , Ph D Lond

From the Department of Public Health and Social Medicine, University of Edinburgh

THIS is a preliminary account of the findings of a public opinion survey carried out in Edinburgh and London between March 11 and March 20, 1957 The survey was designed to assess the extent of the public's information concerning the remuneration of general practitioners, the size of general practitioners' lists, and the finances of the National Health Service, to obtain judgments of the adequacy or otherwise of the income of general practitioners and on the relations between these incomes and those prevailing in other professions, to ascertain what course of action was expected as a result of the current dispute; and to elicit some more general attitudes relating to the N H S and to the place of general practice within it

The interviews were conducted in their own homes with persons whose names had been drawn systematically from the electoral registers In Edinburgh two local-government wards were selected, and 100 names were drawn in each ward, one of the wards (Gorgie-Dalry) was known to house a predominantly working-class population, while the other (Corstorphine) was thought to have a fairly high proportion of middle-class inhabitants In London a sample of 200 was drawn in a single ward, known to be socially heterogeneous, in the Parliamentary constituency of North Kensington When the addresses were visited, it was found that 32 of the people on the London list and 15 of those whose names had been drawn in Edinburgh, had moved from their addresses, in each area 2 had since died Of the remaining 349 individuals, 273 (78%) were successfully interviewed The balance was made up of persons who refused to collaborate (7%), persons who in spite of repeated calls could not be found at home (8%), 3% who were in hospital or too ill to be interviewed and 4% who were temporarily away from home All interviews were carried out with a standard questionnaire, and all had been completed before the British Medical Association recommended a programme of phased withdrawal from the National Health Service

TABLE I *—SOME ASPECTS OF PUBLIC KNOWLEDGE

—	School leaving age of subjects	
	14	15 +
	%	%
Earnings of general practitioners		
Average earnings correctly estimated	21	24
underestimated	54	60
overestimated	3	2
Extent of increase claimed		
Percentage increase correctly estimated	12	16
" " underestimated	44	39
" " overestimated	4	5
Size of general practitioners' lists		
Average size correctly estimated	27	30
" " underestimated	49	47
" " overestimated	6	9
Basis of general practitioners' remuneration		
Known to be based on capitation fee	67	81
Source of N H S finances		
Known to be mainly from taxation	21	35
Believed to be mainly from National Insurance	57	44
Relative costs of G.P. and hospital services		
Hospital service known to be costlier	85	80
G P service believed to be costlier	5	11
N (=100%)	136	132

* Persons whose educational level was uncertain are omitted from this and subsequent tables

Public Knowledge

We may begin by considering how well informed is the general public on some relevant matters of fact The justification for dealing first with this question lies less in its intrinsic importance—though this is not inconsiderable—than in its value in providing a background against which judgments and attitudes can be evaluated

The principal findings under this heading are summarised in table I In this, as in most subsequent tables, the results of the two areas have been combined, and redivided so as to show the influence of educational level on attitude, opinions, and standards of information Only a simple dichotomy is employed, subjects who left school at the age of 14 being contrasted with those whose education lasted until the age of 15 or later †

The general level of public information is clearly unimpressive,‡ and not very heavily influenced by education When asked what was the average income of a general practitioner, after allowing for expenses and before deduction of income-tax, fewer than one in four of the persons interviewed gave an approximately correct answer There was a marked tendency to underestimate the general practitioner's earnings Well over half of all persons interviewed placed the average below £2000 and one in three thought it was less than £1500 By contrast only 6 out of a total of 268 substantially overestimated the average, suggesting that it exceeded £2500 Those subjects who had remained at school until the age of 15 or later were less ready to plead ignorance, but were in fact no better informed than those who had left school at the minimum age

About two in five of all persons interviewed admitted to having no knowledge of the size of the increase in remuneration which had been claimed from the Government, but in fact the extent of accurate knowledge was far smaller even than this would suggest Another two fifths of the sample underestimated the proposed percentage increase, and only 12% of those who had left school at 14 and 16% of the better-educated subjects, came close to an accurate answer The increase claimed was far more commonly believed to be of the order of 10% That the remuneration of general practitioners was based principally on a capitation fee was known to two thirds of the less well educated and to four fifths of the better educated group, about 8% believed that the general practitioner was paid on a fee-for-service basis, and another 3% imagined that he received a salary based on qualifications and experience There was, however, little knowledge of the average size of general practitioners' lists and again the general tendency was to underestimate rather than to exaggerate them Here again education it is better for the patient and the service that a bed should be empty than it should be needlessly occupied But there is every reason for avoiding waste of a bed even for a single day if it can be used The interval between admissions varies between specialties, but (excluding obstetric, chronic, and mental beds) the average in 1954 was 3 72 days Even allowing for the distorting effect of very long periods in a few specialties, this figure seems too high, and it is not falling as much as was hoped Admitting the many potential errors of calculations from national figures, "it is a reasonable proposition that improved admission procedures might save an appreciable amount of time that is now lost"

---

* The London part of the inquiry was organised jointly by Mrs M Jefferys of the London School of Hygiene and Tropical Medicine, and by the Institute of Community Studies, Bethnal Green.

† It should be noted that the two groups are not strictly comparable in respect of age composition There are more young people in the group of subjects who left school at the age of 15 or later

‡ A very high proportion gave an initial "don't know" response to many of the questions and this was reduced by the interviewer who invited informants to choose one of a number of alternative answers

Much improvement has, of course, been made already Dr Godber said that between 1949 and 1955, with a rise of only 1 2% in the number of beds, discharges (including deaths) rose by almost 25% Part of the improvement was due to an increase of available staffed beds from 448,037 to 476,109, but there is no doubt that many hospitals have found it practicable both to shorten stay and to shorten the interval between admissions, and it is evident that "a substantial increase in work done in hospital beds can be achieved without any great increase in their number" In general, our lack is in quality and distribution rather than quantity of beds "We are more than keeping pace with demand and we may expect to reduce the deficit steadily" It is impossible to judge future requirements accurately, because we cannot say how many days of care would be needed if all our hospitals were modern well-planned units but it is significant that in class-I hospitals in New Zealand the treatment of acute medical and surgical conditions took a shorter time than it did in class-II hospitals, which are presumably less well equipped

Sir Harry Platt, P R C S, spoke more forcibly about the obsolescence of our hospitals, in both structure and equipment we are trying, he said, to practise 20th-century medicine in 19th-century buildings On the Continent, since the war, new hospitals—many with interesting features—have grown like mushrooms There developments have been financed by local loans, philanthropy, and central government grants, but with the emphasis on city and local loans In this country we must change the system by which hospital building is financed exclusively from central Government funds if people want the best hospital services, they must pay for them Urging that, in hospital design, account must be taken of changing techniques, Sir Harry mentioned new Canadian hospitals in which an acute unit—not just a few recovery beds—is attached to the operating theatre unit When patients return to the ward three or four days after operation they look after themselves, and the ward is designed so that they can do so

TUBERCULIN-TESTING

To be successful, an epidemiological survey must be simple to carry out, easy to explain to the populace, and capable of reproduction not only in the same country but also in other countries at the hands of other investigators These criteria can be fulfilled in surveys of tuberculin sensitivity by either the Mantoux or the Heaf method Yet little is known about the tuberculin sensitivity of the population of this and other countries, even though, as tuberculosis becomes less common, tuberculin sensitivity becomes more important

Nowadays the most widely accepted test is the intradermal Mantoux using 10 T U Minto [1] used this in 1954 and again in 1955 in his tuberculin surveys in Cumberland—a county with agriculture in the east and an industrial and once "depressed" area in the west In 1953 the death-rates from tuberculosis in these areas were 0 08 and 0 28 per 1000 respectively In that year a mass X-ray survey revealed 2 cases of active tuberculosis (0 07%) among 3015 school-children in the east, and 6 cases (0 35%) among 1692 children in the west In 1954, 73% of the 1102 children aged 5–6 years on the school rolls in east Cumberland were tested, and 7 1% of those tested had a positive reaction, while in the industrial west 69% of the 3177 children on the roll were tested and 10 8% of these were positive reactors In 1955 the tuberculin state of 13 year-old children was investigated Of the 2802 children of this age 78 5% were tested, and the proportions with positive reactions were 20 1% in the east and 36% in the west

Jarman [2] tested the tuberculin sensitivity of school children in the Rhondda Fach in 1950–51 and again in 1953, also taking samples, for use as controls, from a neighbouring valley The standardised percentage of positive reactors aged 5–14 years was 24 6 in the first Rhondda survey and 18 4 in the second, while the figures in the control valley were 20 2 and 18 2 respectively There is evidence that the fall in the Rhondda is unlikely to be due to chance Jarman also noted that the rate of tuberculin *reversion* was 13 4% in the Rhondda and only 2 2% in the control valley—suggesting that improved diagnosis and treatment in the Rhondda have decreased the chances of exposure An associated finding was that the morbidity-rates among children were 1 4% for those tuberculin-negative and X ray negative in 1951, and 4 3% for those tuberculin-positive and X-ray negative in the same year This finding is at variance with the conclusion of most observers—that the attack rate, judged radiologically, is higher among those previously Mantoux-negative than in those previously positive [3]

Bush [4] has shown that the proportion of positive reactors in children in the Los Angeles area rose from 1 1% in 1952 to 2 4% in 1954, though the case rate for all forms of tuberculosis in California fell This rise was attributed to more home treatment, which may allow closer family contacts with the children Furthermore, poorer patients may not be able to continue paying for drug treatment Tuberculin-testing of school children can be valuable not only in detecting unsuspected tuberculosis [5] but also in other ways—for example, by revealing a supply of tuberculous milk [6]

Dr Giannini and Dr Sloan [7] have lately reported from Glasgow that after the age of 34 in women and of 54 in men the proportion tuberculin negative increases with age In 1955, a combined mass radiography and tuberculin survey [8] was carried out in Blyth in Northumberland, and the persons radiographed were encouraged to read their own tuberculin test and report the result by post 20,900 persons were radiographed, representing 60% of the population over the age of 5 95% accepted the tuberculin test and 95% of these returned their cards In all, 40 cases of active tuberculosis were found The analysis of the tuberculin survey is not complete, but it can be expected to show areas where the proportion of people tuberculin positive is above the average, and here the search for source cases must be concentrated

---

THE next session of the General Medical Council will open on Tuesday, May 28, at 2 15 P M, when Sir DAVID CAMPBELL, the president, will deliver an address The Medical Disciplinary Committee will meet on Wednesday, May 29, at 2 15 P M in each of these occupations, and then whether they thought they *should* earn more, less, or the same. A summary of findings is presented in table III. In general we may say that there is a conspicuous tendency to underestimate the incomes of general practitioners in relation to those of other professional groups, coupled with a strong belief that general practitioners deserved higher rewards than most of these other groups. Both belief and judgment are influenced by the level of education. Our better-educated subjects are a good deal less inclined to believe that family doctors receive relatively low incomes, and are also less prone to believe that doctors are entitled to exceptionally high rewards as compared with members of other professions.

The only person on our list who is almost universally agreed both to receive and to merit a higher income than the general practitioner is the surgeon. The only other medical member of the list is in quite a different position. Only about 40% of our subjects believe that the school doctor earns less than the general practitioner, and slightly more of them agree that this is a desirable state of affairs. Judgments of the value of the surgeon may also be contrasted with those of the solicitor. Very few indeed of the people interviewed by us believed that general practitioners on the average received higher incomes than solicitors, but well over half of them thought that they were entitled to higher incomes. The tendency to underrate the value of the solicitor relative to the general practitioner was much less in the better-educated group, which may be presumed to have a clearer understanding of the functions and responsibilities of non-medical professions and a greater appreciation of their value. Again, only one subject in three believed that general practitioners earned more than bank managers, but twice as many believed that they should earn more; in this instance too the better-educated subjects were slightly less inclined to undervalue the non-medical profession. Two-thirds of the people in our sample who had left school at 14, and more than four-fifths of the others, recognised that general practitioners had higher incomes than grammar school headmasters; but while seven in ten of the former group believed this to be an appropriate state of affairs, those who had had a longer educational experience were more evenly divided in their opinions. General practitioners as a group were said to receive higher incomes than university professors by only 9% of subjects with minimal formal education, and by three times as many of the others. The number of subjects in the former group who believed that the family doctor should enjoy a higher income than the professor was nearly five times as great as the number who supposed that this was in fact the case, but in the better educated group the two percentages are very close together.

Perhaps the most striking feature in this list of occupations is the position of members of Parliament. Their standard income has been stationary for many years, and was, one would have imagined, well known to the general public. But among the people interviewed, only a quarter of those who had left school at 14, and less than half of those with a longer education to their credit, knew that general practitioners earned more than members of Parliament, while about two thirds of both groups believed that doctors were entitled to higher incomes than M.P.s. The relative poverty of the minister of religion in comparison with the general practitioner was recognised by almost all persons interviewed, and there were few who believed that the economic positions should be reversed. Only one manual occupation—that of coalminer—was included in our list. More than 70% of persons interviewed knew that general practitioners earned more than coalminers and an even higher proportion thought that they should earn more.

This section of our inquiry throws a useful light on the public's conceptions of the relative income-levels of general practitioners and members of some other professions. These conceptions are often erroneous, and consistently underestimate the doctor's relative remuneration. An analysis of public judgments of desirable relative income levels shows clearly that an extremely high value is placed on the general practitioner. We may recall here that all experimental studies of the prestige ranking of occupations agree in finding that the medical profession is among those accorded the highest degree of prestige. However, in this study the tendency to place general practitioners far ahead of other professions is a good deal less evident in the better-educated subjects.

The Expected Outcome of the Dispute

The high esteem in which the public holds its general practitioners is implicit not only in the economic value placed on their services relative to those of other professions but also in the expressed expectations of their behaviour in relation to the dispute over remuneration. When questioned as to the most likely outcome of the dispute, our subjects most frequently expressed the opinion that the Government would relent and meet the doctors' claim; this view was held by 42% of the sample, irrespective of level of education. But among those who thought this outcome unlikely, the view was not conversely held that the general practitioners would withdraw from the N.H.S. if the Government remained adamant. This belief was restricted to about one in nine of all persons questioned; and for every person subscribing to this view there were three who thought it more likely that the general practitioners would not carry out their threat to withdraw from the service.

TABLE IV—JUDGMENTS OF THE PROBABLE OUTCOME OF THE CURRENT *DISPUTE*

—	School leaving age of subjects	
	14	15+
	%	%
Expected outcome of current dispute		
Government will relent	42	42
G.P.s will withdraw	11	12
G.P.s will not withdraw	37	35
No opinion	10	11
Expected behaviour of G.P.s in event of withdrawal		
Not see any patients	1	1
See only seriously ill	11	14
See all patients, but charge	37	25
See all patients, but charge only some	37	43
See all patients without charge	7	5
No opinion	7	12
N (= 100%)	136	132

We went on to ask our subjects what course of action they thought that doctors would be likely to follow if they did in fact decide to withdraw, and listed a number of possibilities. It is a striking comment on the public conception of the doctor's rôle that of 268 people questioned, only 2 thought that in the event of a withdrawal general practitioners would refuse to see any patients. About one in eight thought that only patients who were seriously ill would be seen, but more than three quarters of our subjects believed that practitioners would continue to see all patients. These were divided, however, as to whether or not a charge would be made. A small proportion—about 6%—thought that a free service would be provided, but the remainder believed that general practitioners would charge some fee to their patients. The most common belief was that they would "charge only those who could afford it." In the better-educated group of subjects, this view was more widely seemed to have little influence on the level of information Slightly more than a quarter of all persons interviewed knew that the average size of list lay between 2000 and 3000 About half believed that the average was less than 2000, and only 7% thought that it exceeded 3000

The illusion that National Insurance contributions pay the greater part of the cost of the N H S was, as might have been expected, widespread, it was shared by more than half of those subjects who had received only minimum education, and by as many as 44% of the others Even in this better educated group only one person in three appreciated that the finances of the N H S were principally derived from general taxation However, few of the persons questioned were in doubt as to which was the more costly of the two major components of the health service, more than four-fifths of all subjects answered this question correctly

Supposed Adequacy of General Practitioners' Incomes

When our subjects were asked to estimate the average earnings of general practitioners, they were also requested to say whether they thought this average income—whatever they supposed it to be—was reasonable in relation to the services at present provided, or whether it was too little or too much As table II (i) shows, practically no-one, whatever his or her belief as to the average income of general practitioners, believed that this average was too high The belief that the average was too low went hand in hand with a tendency to underestimate that average Thus, of the subjects who believed the average annual income to be less than £1500, nearly 70% thought the average was inadequate The corresponding proportion falls to 39% among those whose estimated average was between £1500 and £2000, and to 30% among those whose answers were approximately correct At a later stage in the interview, the correct average was given by the interviewer, and the subjects whose earlier answers had been incorrect, or who had not ventured an opinion, were now asked to judge whether the actual average was reasonable Their answers are combined, in table II (ii), with those of the persons interviewed whose estimates had been correct at the first question We see from this table that only one person in four believed the average to be too low, while more than three in five thought it reasonable Differences in this respect between the different educational groups were almost non existent

TABLE II—JUDGMENTS OF THE ADEQUACY OF GENERAL PRACTITIONERS' INCOMES

(i) Supposed Average Income

Supposed average judged to be	Average income believed to be				
	Under 1000	£1000–1500	£1500–2000	£2000–2500	£2500–or more

Surgeon on hospital staff	10	8	7	7
University professor	9	28	42	33
Member of Parliament	24	44	71	64
School doctor	43	39	51	42
Bank manager	31	36	71	63
Solicitor	13	15	68	50
Minister of religion	79	87	74	76
Coalminer	70	74	78	86
N (=100%)	136	132	136	132

At this point in the interview the range of incomes as well as the average was considered The interviewers pointed out that some doctors with a small number of patients earned only £20 per week, while others with a large number might receive as much as £60 per week, were these incomes reasonable, too low, or too high? The evidence seems to suggest that public opinion as a whole favours a narrowing of the range of incomes of general practitioners That the doctor with a small list deserves a higher reward was agreed by four out of every five persons questioned, irrespective of their educational level So far as the practitioner with a large list is concerned, there seems to be less general agreement, and a greater divergence between educational groups 60% of those who had left school at the minimum age, and just under half of those with a longer educational experience, thought that the higher income was reasonable, but just under one in four of the former group, and slightly more than a third of the latter, considered it excessive

It seems likely that a move towards reducing the variation in general practitioners' incomes, especially by improving the lot of the doctor with a relatively small number of patients, would command considerable popular support In this context it is interesting to note that as many as 79% of all persons interviewed believed that "one general practitioner could not look after 3000 patients properly" Clearly, we cannot attach too much weight to this judgment, in view of the widespread misconception as to the number of patients the average family doctor does in fact look after But it does at least suggest that the balance of public sympathy lies with the practitioner with the small income

As a further step towards classifying public conceptions of the actual and the appropriate income levels of general practitioners, a short list of occupations (mainly professional) was prepared, and subjects were asked first whether they thought that general practitioners on the average earned more, less than, or the same as people in each of these occupations, and then whether they thought they *should* earn more, less, or the same A summary of findings is presented in table III In general, we may say that there is a conspicuous tendency to underestimate the incomes of general practitioners in relation to those of other professional groups, coupled with a strong belief that general practitioners deserved higher rewards than most of these other groups Both belief and judgment are influenced by the level of education Our better educated subjects are a good deal less inclined to believe that family doctors receive relatively low incomes, and are also less prone to believe that doctors are entitled to exceptionally high rewards as compared with members of other professions

The only person on our list who is almost universally agreed both to receive and to merit a higher income than the general practitioner is the surgeon The only other medical member of the list is in quite a different position Only about 40% of our subjects believe that the school doctor earns less than the general practitioner, and slightly more of them agree that this is a desirable state of affairs Judgments of the value of the surgeon may also be contrasted with those of the solicitor Very few indeed of the people interviewed by us believed that general practitioners on the average received higher incomes than solicitors, but well over half of them thought that they were entitled to higher incomes The tendency to underrate the value of the solicitor relative to the general practitioner was much less in the better educated group, which may be presumed to have a clearer understanding of the functions and responsibilities of non-medical professions and a greater appreciation of their value Again, only one subject in three believed that general practitioners earned more than bank managers, but twice as many believed that they should earn more, in this instance too the better educated subjects were slightly less inclined to undervalue the non medical profession Two-thirds of the people in our sample who had left school at 14, and more than four-fifths of the others, recognised that general practitioners had higher incomes than grammar-school headmasters, but while seven in ten of the former group believed this to be an appropriate state of affairs, those who had had a longer educational experience were more evenly divided in their opinions General practitioners as a group were said to receive higher incomes than university professors by only 9% of subjects with minimal formal education, and by three times as many of the others The number of subjects in the former group who believed that the family doctor should enjoy a higher income than the professor was nearly five times as great as the number who supposed that this was in fact the case, but in the better educated group the two percentages are very close together

Perhaps the most striking feature in this list of occupations is the position of members of Parliament Their standard income has been stationary for many years, and was, one would have imagined, well known to the general public But among the people interviewed, only a quarter of those who had left school at 14, and less than half of those with a longer education to their credit, knew that general practitioners earned more than members of Parliament, while about two-thirds of both groups believed that doctors were entitled to higher incomes than M P s The relative poverty of the minister of religion in comparison with the general practitioner was recognised by almost all persons interviewed, and there were few who believed that the economic positions should be reversed Only one manual occupation—that of coalminer—was included in our list More than 70% of persons interviewed knew that general practitioners earned more than coalminers, and an even higher proportion thought that they should earn more

This section of our inquiry throws a useful light on the public's conceptions of the relative income-levels of general practitioners and members of some other professions These conceptions are often erroneous, and consistently underestimate the doctor's relative remuneration An analysis of public judgments of desirable relative income levels shows clearly that an extremely high value is placed on the general practitioner We may recall here that all experimental studies of the prestige ranking of occupations agree in finding that the medical profession is among those accorded the highest degree of prestige However, in this study the tendency to place general practitioners far ahead of other professions is a good deal less evident in the better educated subjects

The Expected Outcome of the Dispute

The high esteem in which the public holds its general practitioners is implicit not only in the economic value placed on their services relative to those of other professions but also in the expressed expectations of their behaviour in relation to the dispute over remuneration When questioned as to the most likely outcome of the dispute, our subjects most frequently expressed the opinion that the Government would relent and meet the doctors' claim, this view was held by 42% of the sample, irrespective of level of education But among those who thought this outcome unlikely, the view was not conversely held that the general practitioners would withdraw from the N H S if the Government remained adamant This belief was restricted to about one in nine of all persons questioned, and for every person subscribing to this view there were three who thought it more likely that the general practitioners would not carry out their threat to withdraw from the service

N (= 100%)	136	132

We went on to ask our subjects what course of action they thought that doctors would be likely to follow if they did in fact decide to withdraw, and listed a number of possibilities It is a striking comment on the public conception of the doctor's rôle that of 268 people questioned, only 2 thought that in the event of a withdrawal general practitioners would refuse to see any patients About one in eight thought that only patients who were seriously ill would be seen, but *more than* three quarters of our subjects believed that practitioners would continue to see all patients These were divided, however, as to whether or not a charge would be made A small proportion—about 6%—thought that a free service would be provided, but the remainder believed that general practitioners would charge some fee to their patients The most common belief was that they would "charge only those who could afford it" In the better-educated group of subjects, this view was more widely held than the alternative expectation that all patients would be expected to pay a fee, among those who had left school at the age of 14, the two views were held with equal frequency

If a fee was to be charged for each consultation, how much was it likely to be? In respect of both surgery and home consultations there was a considerable difference of opinion between the two social groups, but it was the less well educated subjects, with their more modest estimations, who proved the more accurate prophets In this group, the most common estimates were *5s* for a surgery consultation, and *7s 6d* for a home visit, although at least a fifth underestimated both charges, while 15% expected that a surgery attendance would cost *10s* or more and as many as a quarter that the fee for a home visit would fall into this bracket In the group of subjects who had remained at school at least until the age of 15, 36% expected a surgery consultation to cost in the neighbourhood of *10s*, while only 30%, compared with half of the less well educated group, thought the fee was likely to be *5s* or less Again, 45% of the better educated group expected that the charge for a home visit would be *10s* or more, and two-thirds of these thought the fee was likely to be at least *15s*

So far as statements of intention provide a reliable guide, the imposition of a consultation fee seems likely to reduce the volume of the general practitioner's work, though not perhaps as heavily as some would suppose About a quarter of the less educated—and on the whole less well paid—subjects expected that if fees were introduced they would consult their doctors less frequently, this was also the belief of only one in eight of the better-educated subjects, in spite of the fact that they expected a higher scale of fees Another rather revealing finding of this section of our inquiry is that about 70% of our persons questioned did not believe that the introduction of fees would affect the quality of general practitioners' work The view that under such a system the general practitioner would take more time and trouble with his patients was held by only 27% of our subjects This view was slightly more commonly found among those with only minimum education, but even in this group it appears with less than half the frequency of the opposite view In general, the public is confident that the dispute with the Government will not affect the availability of general practitioners' services, and believes that the quality of this work does not depend upon the basis of remuneration

Some Views on the National Health Service

It is clear that there are no widespread public beliefs concerning the relation between the quality of medical care and the nature of its administrative and financial context This is indicated not only by the common view that a fee paying system would not improve the quality of general practice, but also by retrospective judgments of the effect of the N H S on medical care Half of all persons interviewed believed that there had been no significant change, while the remainder were more or less evenly divided between those who thought there had been an improvement, those who believed there had been a deterioration, and those who had no opinion It is perhaps significant that among those members of the sample who were less well educated—and on the average less well placed socially and economically—the view that the quality of medical care had improved since the introduction of the N H S was twice as common as in the other half of the sample The higher proportion of "no opinions" among the better educated subjects reflects the greater number of young people in this group who were not in a position to make any comparison

Asked which was the more valuable part of the N H S —the fact that all members of the community now had access to the services of a general practitioner without charge, or that everyone was entitled to free hospital treatment—a substantial *majority cast its* vote for the hospital This latter view was held by three fifths of the persons interviewed, as compared with about a quarter who believed that access to general practitioners, unrestricted by economic considerations, was the more valuable The question was framed in economic terms, and most of the replies were prompted by a consideration of the probable cost of hospital treatment But this should not be taken to mean that the hospital is in some sense preferred to the general practitioner Our subjects were asked whether, if they were to have a course of treatment which could be given either by their own general practitioner or at a hospital outpatient department, they would prefer one or the other In this context about 70% expressed a preference for their general practitioner, more than three times as many as preferred the hospital The former preference was sometimes explained in terms of convenience and proximity, and sometimes in terms of specific objections to the hospital, but far and away the commonest reason for preferring the general practitioner was that he had a personal knowledge of the patient and gave a closer personal attention to his needs; this was often contrasted with the anonymous and impersonal nature of the hospital situation.

Finally, we asked our subjects whether they wanted the National Health Service to continue as at present, or whether they would prefer to pay for their own medical care. Four-fifths of the people interviewed, irrespective of social level, wanted to see the service continue.

Summary

A brief account is presented of the results of 268 interviews with members of the general public on the subject of the remuneration of general practitioners and the current dispute between them and the Government. The names of the sample were drawn from electoral registers in Edinburgh and London, districts being selected so as to yield a final sample with a higher representation of middle-class groups than might be expected in a random sample of either city.

The level of public knowledge concerning some of the basic facts relevant to the dispute is unimpressive, and the better-educated members of the sample are not very much better informed. The errors are not random, however. The average earnings of general practitioners, the magnitude of the increase claimed by the medical profession, and the average size of the general practitioners' lists are consistently underestimated. The National Health Service is widely believed to be financed mainly from National Insurance contributions.

The average income-level of general practitioners is thought to be adequate by more than 60% of the sample, and to be too low by about a quarter. The incomes of doctors with small lists are almost unanimously agreed to be too low.

A comparison of the incomes of general practitioners with those prevailing in other professions shows a tendency for doctors' earnings to be underestimated relative to those of other groups and for their comparative economic worth to be very highly rated. Both these judgments were appreciably less common in the better-educated subjects.

Few thought it likely that general practitioners would withdraw from the National Health Service, and it was widely expected that one or the other side would relent. Opinion as to the most likely consequences of withdrawal was divided, but a large majority agreed that doctors would continue to see all their patients, and charge fees to either all or some of them. The better-educated members of the sample expected a higher scale of fees than did the other subjects, who were in fact more often accurate in their predictions. A substantial majority agreed that the introduction of fees would affect neither their own use of the general practitioner's services, nor the quality of those services.

There was no consensus of opinion as to the effect of the National Health Service on the quality of the medical services, about half our subjects supposing that there had been no significant change. The hospital service was considered, on economic grounds, to be the most valuable part of the service, but most people interviewed would prefer to be treated by their general practitioner rather than at hospitals. An overwhelming majority preferred a continuation of the National Health Service to a fee-paying system.

Our thanks are due to the Institute of Community Studies and Mrs M. Jefferys for their organisation of the London interviews, and to Mrs. Jefferys and Dr. Cecil Gordon for many valuable comments and suggestions.

CLINICAL RESEARCH

THE Ministry of Health has issued a memorandum[1] describing arrangements for coördinating and financing clinical research at hospitals in the National Health Service.

The Minister hopes that hospital authorities will do all that lies in their power to foster clinical research in their hospitals. But these authorities have research powers only under section 16 (2) of the National Health Service Act, 1946, and they have no power to assist by grants or otherwise any persons or body to carry out research which is not "conducted" by the board or committee.

> "The research can be carried out by the Board or Committee alone acting through their own officers, whether regular hospital staff or specially employed, or in conjunction with another body. The circumstances must be such that it can reasonably be said that the Board or Committee, alone or in conjunction with someone else, has promoted or sponsored the research project and has general control over its character and the carrying out of it. While, therefore, there are ample opportunities for Boards and Committees to combine with other bodies in research work, they cannot make grants to bodies in respect of research conducted solely by those bodies."

The Minister does not intend by his recommendations to limit the conduct of research by boards and committees at the cost of their non-Exchequer funds, but, having regard to the need for coordinated development, the hospital authority or the appropriate research committee should not hesitate to seek advice from the Clinical Research Board about schemes proposed to be financed from non-Exchequer funds.

CENTRALLY ORGANISED RESEARCH

One function of the Clinical Research Board is to help the Medical Research Council in organising major clinical research financed from Exchequer funds and to recommend to the Council any clinical research units—existing or proposed—for which the Council should be responsible. "Major research," says the memorandum, may be broadly defined from the white-paper[2] which led to the setting up of the Clinical Research Board. This said that hospital authorities should be debarred from paying salaries of whole-time research-workers above the grade of senior registrar, and a limit of £1000 annually should be placed on individual grants for assistance and expenses.

Following a review by the Clinical Research Board, major schemes that were being conducted by hospital authorities are being transferred to the Medical Research Council. "It is particularly requested," says the memorandum, "that all proposals for new major schemes to be financed from Exchequer funds should be referred to the Clinical Research Board and that no new commitments should be entered into in this field without prior consultation with that body."

When it is decided to establish new clinical research units at hospitals, it is for the M.R.C., advised by the Clinical Research Board, to make the necessary arrangements with the hospital authorities, including arrangements for consultation with the board or committee on the appointment of members of the unit. But "it does not follow that all major research schemes would be initiated by the central organisation. Many schemes start from proposals made by an individual clinician who may put proposals to a Hospital Board or Committee for submission to the Clinical Research Board or may apply direct to that Board."

Hospital authorities will be responsible for providing clinical facilities for the units of the central research organisation This will entail honorary contracts for those members of the research units who must have access to patients, and it may sometimes require strengthening of the *hospital* clinical staff Where a board or committee considers that extra clinical appointments are necessary to cope with the additional hospital work imposed by research requirements and, for example, where a highly specialised type of treatment attracts more patients to the hospital, the hospital authority will no doubt consult the M R C and where necessary make proposals to the Minister for an increase in establishment In small clinical research units the director alone will normally be eligible for the status of honorary consultant, but exceptionally a senior assistant may also qualify for this status, and in large units one or more of the senior workers may also qualify The grading of all honorary appointments should be decided in agreement with the M R C A research-worker with the status of honorary consultant will be eligible for a distinction award

[2] Clinical Research in Relation to the National Health Service. H.M. Stationery Office, 19 . See *Lancet*, 1953, ii, 123, 13

LOCALLY ORGANISED RESEARCH

In conducting locally organised research, hospital authorities should pay special regard to the recommendations in the 1953 white-paper that each regional board and each board of governors should set up a research committee, after consultation with the associated university or medical school, to advise on the spending of money from any source which the board has available for research, and that, where convenient, a regional board and a board of governors might set up a joint committee to serve them both Management committees which wish to undertake research, however financed, should put forward proposals to the regional board for consideration

Hospital boards are to receive from the Exchequer a specific annual allocation for locally organised research To enable the Minister to decide on an appropriate allocation for 1958–59 and subsequent years, boards are to submit annual reports on locally organised research undertaken at the expense of Exchequer funds These reports will be the subject of consultation with the Clinical Research Board, so that, in agreement with that body, the Minister may from time to time (generally at five-year intervals) reassess the annual allocations to ensure that they are directed to the hospitals where "the right men and facilities are available" In their reports boards should include information about research conducted by them from non-Exchequer funds in order to give a complete picture of the work in progress

Although a board should not find it necessary to employ clinicians above the level of senior registrar for the sole or primary purpose of research, there is no objection to its arranging for a consultant, S H M O, or S H D O to undertake research which is incidental to his clinical employment Where such a doctor or dentist is employed part time on his routine work, he should be remunerated for research by a lump sum payment, renewed if necessary at intervals

RESEARCH FROM NON EXCHEQUER FUNDS

The Ministry suggests that research paid for from non-Exchequer funds might be subjected to the following broad considerations which apply to research paid for by the Exchequer (1) advice from a joint research committee set up in agreement with a university or medical school, (2) an approved programme on broad lines in cases where lump sum grants are to be paid to research workers, (3) periodical progress reports to the body or bodies financing the research, and (4) inclusion of information about such research in reports to the Minister These suggestions are "not intended in any way as a measure of limitation or supervision of the powers of Boards and Committees to use non-Exchequer funds for research in accordance with the provisions of Section 16 (2) of the National Health Service Act"

OTHER ARRANGEMENTS

A part-time consultant, S H M O, or S H D O wishing to carry out research in his own time may, instead of seeking to make arrangements with his board, apply direct to the M R C for financial help or for a part time appointment on the Council's staff

Any suitably qualified person in the hospital service may apply to the M R C for a grant to cover the expenses or technical assistance required for a research project

FALLOUT FROM BOMB TESTS

In a paper to the American Physical Society on April 26, Dr WILLARD F LIBBY, commissioner of the United States Atomic Energy Commission, discussed in detail the present sum of knowledge about radioactive fallout and its effects From his assessment of the data so far collected, Dr Libby concluded that the risk from nuclear testing at the present rate was small

He said that the present body burden of strontium 90 in new bone in the United States from atomic tests corresponded to the increased dosage to the bones from cosmic rays which would result from an increase of some 400 feet in altitude, and the present vital statistics showed no observable effect on the occurrence of bone cancer or leukæmia of much larger changes in altitude The tolerance figure of 100 "sunshine" units (100 micromicro curies per g of body calcium) that was now recommended was about two hundred times the present level for new bone in the United States, and it would not be exceeded by fallout from weapon tests in any foreseeable circumstances

The effect of locality was important, particularly the effect of calcium deficiency in the soils Careful consideration of this question indicated that there would be very few individuals with a strontium-90 content which was strictly inversely proportional to the available calcium concentration of the soil in their region The explanation was that food distribution systems automatically averaged over a wide area and people assimilated their calcium slowly Most people drank milk and ate cheese and other calcium-bearing foods from a rather wide area, and this effect reduced by an estimated factor of ten the potential effect of calcium deficiency in the local soils

Laboratory experiments suggested that the human body concentration of strontium 90 at equilibrium would be between 13 and 30 times less than that in the top soil The present data indicated that the higher figure was closer to the truth, and a conservative estimate for this ratio would be 20 Therefore, the present burden of 50 sunshine units in the top soil of the United States may eventually lead to as much as 2 5 sunshine units in the human bones, but more probably it would lead to about 1 7

The strontium 90 still in the stratosphere would fall out, Dr Libby expected, at a rate which just about compensated for the decay of the material already deposited, so that no great additional increase from this source was to be expected from weapons fired in the past If the testing continued at about the same rate as it has averaged over the past five years, then an equilibrium rate of fallout would be reached after an infinite time, and that rate would be 8 times the present one In other words, in the United States something between 5 and 20 sunshine units would be the equilibrium concentration of human bones if testing continued indefinitely at the average rate of the past five years This level would be approached only after a few decades After 28 years the level would be half of this equilibrium value, and in the year 2008 three fourths of the equilibrium figures would have been reached Thus, somewhere between 4 and 15 sunshine units in human bones in the United States might result from the present type of testing being continued for the next fifty years

In those parts of the world where the soil was low in calcium, this level might increase by as much as five times At the present rate of testing it might indeed approach the figure of 100 sunshine units, the tolerance limit for large populations, at the beginning of the 21st century for these certain limited regions in the world But, Dr Libby added, the observed conditions in these regions could be relieved by fertilisation of the soil with calcium, either calcium nitrate or lime being used

Conferences

DECISIONS DEFERRED

Special Representative Meeting of B M A

In its decisions about what course the remuneration dispute should take, the special representative meeting of the British Medical Association on May 1 was not as decisive as expected New developments were put before it, and, though some representatives were doubtful whether the situation was thereby changed, the meeting decided to defer a decision on the plan for progressive withdrawal of general practitioners from the National Health Service , and it also agreed to postpone the question of evidence or no evidence to the Royal Commission until the next representative meeting

Dr Solomon Wand, chairman of the council of the B M A , reviewing the events that had led to the present position, said that the profession's claim had been met by the appointment of a Royal Commission and two acts of dictation—the 5% and 10% interim awards An honourable profession had been treated with contempt and driven into a defensive action thoroughly distasteful to every one of them , but that action had been justified

NEW DEVELOPMENTS

In recent weeks Dr Wand had had talks with the Minister of Health and with the chairman of the Royal Commission, Sir Harry Pilkington, in an attempt to find a solution One outcome of these discussions was a letter dated April 26 from Mr Vosper to Dr Wand, and this letter, it seemed, was one of the main reasons why the B M A council withdrew its original recommendation to the meeting and substituted one which advised deferment of decisions on the Royal Commission and on withdrawal This letter, read as follows

> Dear Dr Wand,
>
> I was glad of the opportunity of a long talk with you yesterday and I hope you feel—as I do—that it is that kind of informal and personal discussion which does most to clear away misunderstandings
>
> First, let me confirm what I said to you when I assured you that, following the report of the Royal Commission, there will be full consultation with the profession before implementation of any of its findings and that such consultation could of course include any matters relevant to the report or the present dispute
>
> Second, you seemed to fear some inconsistency between the terms of reference of the Commission and the public statements issued by its Chairman I can certainly reassure you here too It is normal that the interpretation of the terms of reference of a Royal Commission should be a matter for its Chairman and the Commission, and you can certainly regard the public statements which have been issued as having full validity
>
> Finally, I have thought—as you asked—about the position of the public health medical officers I cannot add anything of substance to what I said in my letter of 17th April on this, but let me repeat that I am sure that any settlement for others, following the Commission's report, could not fail to be taken into account in considering the position of these officers and any claim through the normal machinery would of necessity be considered in the light of the report and of any settlement subsequent to it
>
> I do hope that these remarks, and our talk yesterday, will help to rid us of unnecessary apprehensions
>
> Yours sincerely,
> Dennis Vosper

Another development which had influenced the situation was an additional statement from Sir Harry Pilkington

> "That part of the Royal Commission's task that consists of considering what should be the proper current levels of remuneration of doctors and dentists will include hearing submissions from those professions as to the remuneration which they are now claiming."

At the same time the chairman had made it plain that the Commission did not and would not regard itself as an arbitrating or adjudicating body He had also said that if it became unlikely that a report could be published by Easter, 1958, he would so inform the Government and other interested parties

Discussing these events, Dr Wand said that, despite the facts that the claim had not been met and that Spens was in the melting-pot of the Royal Commission, the gains were not inconsiderable The terms of reference had been broadened (in a way that was probably unprecedented) , a time-limit had been set for the report , the validity of the chairman's statements had been confirmed , full consultation had been promised before implementation of the Commission's findings , and the Government had made interim awards

The present issue, to Dr Wand's mind, was "give evidence or withdraw" A third alternative—to do nothing—was not, he thought, in the minds of most of the profession Whatever decision the meeting took the struggle was not yet over and the need for closing the ranks of the profession was as great, or greater, than before

ROYAL COMMISSION

The council put before representatives the following recommendation

> That in the opinion of this meeting circumstances have so changed that the position has altered since the council issued its recommendation to the representative body not to give evidence to the Royal Commission, but, realising that divisions and the profession generally have not had an opportunity of considering the statements by the chairman of the Royal Commission or the letter (April 26, 1957) from the Minister of Health to the chairman of council, this special representative meeting defers a decision on the question of giving evidence to the Royal Commission until the next meeting of the representative body

But whether "circumstances have so changed" proved a point for much argument, and a move to delete any mention of change from the recommendation was widely supported, most forcibly perhaps by Dr B Burns (Sheffield) Conditions were not altered, he declared, by "a form of words" "Spens to be the basis of general practitioner remuneration" that had been a form of words "Negotiations on terms of service" that had been a form of words And forms of words had lured the profession into a "paradise" in which they were the doormats of the Welfare State If doctors cooperated with the Royal Commission they would have discussed an alternative to Spens—and that was where the politicians wanted to get them Dr O C Carter (Bournemouth) thought that one phased withdrawal was being replaced by another—withdrawal of the profession's resistance If doctors gave in now, they could never in the future resist unilateral action by the Government Dr F S Rickards (Lancaster) spoke of 5% and 10% gobstoppers to keep the profession quiet Doctors were proving tough and the

Government was beginning to respect them for it Dr H Guy Dain (Birmingham), however, was sure that things *had* changed the Royal Commission amounted to effective arbitration, he declared—but amid cries of dissent The move to modify the council's recommendation was defeated by 163 to 199

An amendment frankly in favour of cooperation with the Commission was then debated Dr A H Hall (Brighton), president of the B M A, said that the efforts of Dr Wand and others had narrowed the gap in the *dispute and he hoped that it could be narrowed still* further—but not, he was sure, without the aid of public opinion, which should not be ignored in the meeting's decisions

Dr Talbot Rogers (Bromley) confessed that he had had serious doubts about the Royal Commission because of the probable delay in the appearance of its findings and because of the difficulty of deploying the profession's arguments before it But these doubts had been completely resolved The doctors had got to give evidence some time and Dr Talbot Rogers hoped they would give it soon Dr A B Davies (Walsall and Lichfield), who succeeded Dr Talbot Rogers as chairman of the General Medical Services Committee, said it was highly desirable that the meeting's decision should accord with that of the Special Conference of Local Medical Committees held on the previous day[1] (the conference had decided to defer until June a decision on the Royal *Commission and on withdrawal*)

Prof H W Rogers (Belfast) said his division had instructed him to vote against cooperation, but his own feeling was that to give evidence would provide doctors with a much better opportunity of having their claim heard He thought it would be selfish, however, for some people who, like himself, were already getting an adequate salary, to claim a penny more Doctors should raise their eyes from the mire and bitterness and try to help the country as a whole

Mr T Holmes Sellors, chairman of the Central Consultants and Specialists Committee, said his committee had reversed a previous decision against cooperation, and the Joint Consultants and Specialists Committee had asked its constituent bodies to prepare evidence

Several speakers were concerned at the damage cooperation with the Royal Commission might do to the public health doctors Dr H D Chalke (London) recalled a unanimous decision, at the last representative meeting, to "stick together" Now the public-health doctors were in danger of being thrown to the wolves

Finally, the meeting decided to accept the council's recommendation without reservation or amendment

WITHDRAWAL

Moving the council's second recommendation—to defer a decision on withdrawal—Dr Wand emphasised that a date on which a decision *would* be taken had been deliberately omitted from the wording of the recommendation It was a strong resolution a date could easily be determined after consultations—or the breakdown of consultations—when the Royal Commission had reported Many amendments concerned with withdrawal on the original agenda were not discussed, but it was agreed to ask the Central Consultants and Specialists Committee "to take active steps towards a special levy in proportionate amount to help in the present remuneration crisis" And the B M A council was asked to use all its efforts to increase the Defence Trusts If any of the representatives had a mind to call for an immediate decision to withdraw, they kept it to themselves, and the meeting quickly approved the council's recommendation

A LEGAL FIGHT ?

Though the fire seemed to have gone out of the meeting, Dr J A Gorsky (Westminster) struck quite a spark with his robust plea for the institution of legal proceedings to establish whether the Spens reports constituted a legally implied contract The surrender of rights by doctors when they entered the National Health Service must, he claimed, have some significance in law, and he thought that the Spens report for the general practitioner constituted a legally valid contract The profession should ask the High Court for a declaratory judgment to that effect

Dr W N Leak (Mid-Cheshire) read to the meeting the much quoted paragraph 179 from the Ministry of Health *Handbook for General Medical Practitioners* This paragraph, according to Dr Gorsky, was admissible in a court of law

> "The Central Pool is now calculated on the basis of the estimated net remuneration appropriate for general practitioners in 1939 (as recommended by the Spens Committee in 1946) together with a betterment factor taking account of changes in the value of money since that time This amount is adjusted to take account of changes in the number of general practitioners participating in the Service, their estimated remuneration from other sources, and the superannuation contributions made by the Exchequer"

Dr Wand said that Dr Gorsky's points had been in the minds of the council in recent weeks Eminent legal opinion had been against going to court, but if another counsel were to be consulted and if he said that there was even a small reasonable chance of success, then it might be the thing to do If legal advice was against going to court, it would be foolish to do so The meeting was keen to see the prospects of legal action examined further, and Dr Gorsky's plan was referred to the council

Public Health

Adolescents

At the Royal Society of Health congress, held at Folkestone on April 30 to May 3, Mr W Emrys Davies, PH D, described how, with the forthright spirit of our times, he had challenged his teen-age pupils to uncover anonymously the pattern of their private lives, and with the trust and frankness of youth they had done so How far the children of a comprehensive school on a large Manchester housing estate are typical of youngsters in the rest of Britain is unknown, but there seems no reason to think that Wythenshawe's are any better or any worse than their contemporaries elsewhere Indeed it is popularly believed that children in the south of England reach social maturation and sophistication earlier than their northern brothers and sisters Whether that is so or not, Dr Davies's findings at least point to the broad trends in our social progress, and they are not without medical significance if we can bring ourselves to face realities

The home background of the youngsters was mainly in social classes III and IV, 82% of the fathers being skilled or partly skilled, and the age-groups questioned were the 13½–14½ or the 14½–15½ cohorts Most groups contained about 190 pupils, but some selective inquiries were much smaller On that account many of the results should perhaps be viewed with reserve

Dr Davies asked his 13½–14½-year olds how they spent their spare time, and what were their major interests outside school Physical activity in one form or another still held the interest of 60%, the other 40% had already acquired the more sedentary pursuits of British adult life today Television and cinemas attracted both sexes fairly equally, but while the rest of the girls were starting to look for boy-friends, or occasionally reading, their male contemporaries were consoling themselves by making things with their hands Reading anything more than comics featured little in their boyhood lives It was another year before the boys became more girl-conscious At $14^1/_2$-$15^1/_2$ years of age, 60% of boys and girls chose either companionship of the opposite sex or mixed parties

---

[1] See *Lancet*, May 4 1957 p 927

It was found that a third of the $13^1/_2$–$14^1/_2$ age-group had nine or less hours' sleep, and Dr Davies suggested that this was too short a time for growing bodies and active minds Whether a child comes to terms with sleep requirements is the parents' responsibility, but it is the schoolmaster who gets the backwash Early to bed was never a popular cry, and perhaps less so nowadays when the hypnotic television screen stirs up sex and violence until nearly 11 P M

There is evidence of early recourse to sedatives 5% of the $13^1/_2$–$14^1/_2$-year-old group admitted taking sedative drugs regularly, and another 36% occasionally If that is what happens with the odd bottle of pills in the bathroom cupboard, what will happen when the flood tide of tranquillisers crosses the Atlantic? If smoking can be regarded as a sedative, and not merely a display of teen-age bravado, nearly half of the boys and a fifth of the girls in the $14^1/_2$–$15^1/_2$ group had acquired a taste for smoking, and indeed that taste might already have developed into a habit So much for the progress of the campaign against lung cancer Stimulation with alcohol had already started in the same age-group Of a sample 33 boys and 32 girls, 41% seldom had a drink, 32% admitted occasional indulgence, 15% drank regularly, and 5% did so both regularly and frequently

Answers on personal hygiene were illuminating 65% of the youngsters bathed only once a week. Hand-washing after toilet was practised always by 34%, usually by 55%, and seldom by 11% Teeth-cleaning was disappointing 39% brushed their teeth either occasionally or never, 35% did so once a day, and only 25% observed did so night and morning, 3% of the girls did so more than twice a day Sharing hair-combs was very prevalent in both sexes, but communal life no doubt encourages the practice of borrowing items of personal toilet

The answers to these questions may suggest fresh lines of approach We must recognise the earlier social maturation of our teenagers and realise that it is developing unevenly If heterosexual interests are being aroused earlier than in our own generation it is no use blinding ourselves to the fact Surely there is scope to play on the vanities of awakening consciousness to get across the basic points of personal hygiene and bodily health, this is no more than is done for the adult population by the advertisers of cosmetics, deodorants, drugs, and fancy foods If grown-ups are most easily taught through the medium of strip-cartoons, eye-catching posters, slogans, and television, why should children be fed with less exciting fare? We are still a long way behind commercial practice with our market research

It would be equally unrealistic to assume that youngsters know all the answers Dr Davies proved that they do not Outline anatomy of the human body was only hazily understood by most of the $14^1/_2$–$15^1/_2$ age group, and knowledge of basic physiology was even scantier In the $14^1/_2$–$15^1/_2$ age-group 75% of the boys and 94% of the girls registered a strong desire to learn more about the development and functioning of the human body No-one can blame them for their ignorance of this subject, and by their answers they threw the challenge squarely back to us

Scotland in 1956

Provisional statistics for last year have been issued by the Registrar-General for Scotland [1] The birth-rate was 18 5 per 1000 population, which was 0 5 above the rate for 1955 The stillbirth-rate was 24 per 1000 live and still births—1 less than that for 1955 The death-rate (12 0 per 1000 population) was the same as that for 1955 The infant-mortality rate was 29 per 1000 live births, which was the lowest ever recorded, and the neonatal-death rate was 19 per 1000—1 less than in 1955 The death-rate from tuberculosis was 16 (respiratory 14, non-respiratory 2) per 100,000 population

A Primer in Public Health

Dr A. R Southwood, director-general of public health in South Australia, has written a booklet [1] for the guidance of newly appointed medical officers of health It is in simple, at times breezy, language, and covers a wide field, with ample quotations from authors as various as Percival Pott, Charles Dickens, and J S Mill Some of the material has special application to South Australia, and some of the rest will be familiar to any doctor, but the medical officer of health in this country may find the clear presentation useful in his activities in health education

Parliament

The National Health Service Contribution

As has already been announced, the Government proposes to introduce a Bill to institute a separate National Health Service contribution and to double the 10*d* which is at present allocated to the service from the present joint National Insurance contribution Since the proposals are an increase in amounts paid into the Exchequer the Bill has to be founded on a Ways and Means resolution, and in introducing this resolution on May 1 Mr J **Enoch Powell**, financial secretary to the Treasury, pointed out that the National Health Service element had always stood on a different footing from the rest of the combined payment Unlike the rest of the contribution, it was paid from the Fund, where the rest remained, into the Exchequer, it did not constitute a qualification for receiving benefit, and, finally, whereas the rest of the combined payment was designed to meet the whole cost of the insurance benefits, it was never contemplated that this element should represent more than a fraction of the cost of the National Health Service There had been a good deal of misunderstanding and misapprehension as to the nature, the amount, and the effect of the National Health Service element, and he thought it sensible that its entirely separate nature should be formally and explicitly recognised In his report in 1942 Lord Beveridge had written

> "There is no obvious reason apart from a desire to keep the insurance contribution as low as possible, why insured persons should be relieved of this burden wholly, in order that they may bear it as taxpayers If importance attaches to preserving the contributory principle for cash benefit it attaches also to contribution for medical treatment There appears to be a case for including part of the cost of domiciliary treatment in the insurance contribution."

---

[1] Quarterly return of the Registrar General Scotland for the quarter ended Dec 31 1956 also preliminary return for 1956 H M Stationery Office Pp 40 2s 6d

[1] Southwood A R The Bases of Public Health Published by the Department of Public Health Adelaide 1957 Pp 84

Lord Beveridge had recommended that 10*d* should be included in the weekly contribution for the purposes of the National Health Service, and it had been expected that this contributory element of finance would represent about a quarter of the gross cost of the entire service. But the gross cost of the service had risen from £170 million to £690 million, so that the yield of the 10*d* today represented, not nearly a quarter, not something over 20% as was the intention of the 1946 Bill, but 5·8%. Mr. Powell agreed that when the increase in the gross national product was taken into account, the increase in real cost of the service was of course not so large as the gross figure suggested. But this did not affect the ratio of the gross cost which was financed by these contributions. It was, however, fair to take into account the charges now paid by patients. But even these payments and the contributions together only accounted for just over 11% of the gross cost of the health service, or scarcely more than half the amount which it was intended should be yielded by the contributory element. The increased contribution and the yield of the charges would still only represent some 17% of the gross cost.

The constitution of a separate National Health Service contribution, he added, would have an effect on the parts of the contribution eligible for taxation relief. Except for an employer engaged in trade or business, the National Health Service contribution would not in future rank as an allowance for tax purposes. In his view this change was logical because the benefits for which contributions were paid would be tax-free. Again if the N.H.S. contribution could count as an allowance it would mean that the higher taxation was, the more tax a person paid, and the higher his income was, the less he contributed towards the maintenance of the National Health Service.

Miss MARGARET HERBISON, who objected to the new contribution, pointed out that, though the gross cost of the National Health Service had risen, the proportion of the national income that went to it had fallen from 3·51% in 1948–49 to 3·24% in 1953–54. In the light of these figures it seemed to her that the Government had no case for raising the contribution. In particular, they had no case for imposing it on the low-wage earners, who would find it in the nature of a poll tax which they would be ill able to pay. Dame IRENE WARD seized the opportunity to ask what proportion of the new payment would come to her region—the Newcastle Regional Hospital Board—which when the N.H.S. started received a smaller share than more fortunate regions because it had fewer hospitals and fewer specialist services. Mr. ARTHUR BLENKINSOP, with local patriotism but little hope, supported her plea. The regional board was, in his view rightly, concerned that it had not been able to expand its specialist services. It had been restricted not only by the size of its allocation but also by the direct fiat of the Ministry of Health which was denying it opportunity to make appointments which, especially in the psychiatric service, were urgent. He feared that it was now the Government's object to finance the National Health Service in large part out of insurance contributions and charges. He believed that it was fairer to meet the undoubtedly heavy, but not unreasonable, cost of the service out of general national revenue. He feared that we were getting back to an insurance scheme, rather than maintaining the kind of National Health Service we had in mind in 1946.

Mr. RAYMOND GOWER thought that we were fortunate compared with countries which did not possess a health service, but we must be realistic. It would be dangerous if we got rid of our financial difficulties in financing the service by adding the cost to the general burden of taxation since we were so heavily taxed already.

Mr. DENNIS VOSPER, the Minister of Health, said that he did not wish to anticipate the speech he would make when introducing the Bill. But he reminded those who talked of hardship that between 1946, when the contribution was fixed at 10*d* and 1956 there had been an increase in wage-rates of 70% and in earnings of 99%. Today the increase was still greater, therefore it seemed reasonable that there should be an increase in the contribution. The Government were anxious to establish in the minds of the public the part of the contribution that went to the health service, and the stamp would, in some form as yet to be determined, make this clear. But this increase in the contribution was not an increase in the total National Health Service finance. The contribution, in fact, would be only sufficient to meet the estimates of regional hospital boards already approved by the Ministers.

In his view the Opposition must face the fact that, if they were not prepared to increase taxation to a considerable extent to finance the whole of the National Health Service, they might have to increase the charges to patients. It would be possible for the Opposition to propose a hospital boarding charge. Was that in their minds? The House had not heard the answer. The Government's policy was that the health service should be financed in part, but in part only, by direct contributions paid by those who were fit and at work, and he believed that that was something which commended itself to the great mass of opinion of this country.

Radioactivity and Food Contamination

In a debate on the adjournment on May 8 Mr. HECTOR HUGHES asked the Government what steps were being taken to preserve the world's food-supply from contamination by strontium 90 released by hydrogen bomb tests. Mr. J. B. GODBER, joint parliamentary secretary to the Ministry of Agriculture, Fisheries, and Food, said that research into non-medical biological hazards caused by radioactive substances was sponsored by a committee under the chairmanship of Lord Rothschild, the president of the Agricultural Research Council. The committee had been set up jointly by the A.R.C., the Medical Research Council, and the Development Commission, and its members included experts from these bodies and the Atomic Energy Authority.

Any danger from hydrogen-bomb tests, he said, resulted from the gradual radioactive fallout from the upper atmosphere. At present the danger of contamination of fish landed at our ports was negligible. The radioactive particles carried to the upper atmosphere by explosions in the Pacific and other distant areas drifted to all parts of the world before being deposited very gradually over a period of years on the earth's surface. In 1956 the A.R.C. embarked on a field trial at the Compton research station on the uptake of radiostrontium from the soil by barley, grass, and sugar beet. The actual form of radiostrontium used for these experiments was strontium 89, which had a half-life of 54 days compared with strontium 90, which had a half-life of 28 years. This reduced the hazard and ensured that the land would not be put out of use permanently for agricultural purposes. The effects were identical. This experiment would give fundamental knowledge for the guidance of farming practice in the event of agricultural land becoming contaminated either by fallout from nuclear attack or from an accident to an atomic power-station. The chance of such an accident was remote but we must be prepared. The results had not yet been published, but he could say that the uptake of radiostrontium by the plants grown was less than 1% of the amount put down.

The soil at the Compton station was chalk downland, and the results were to be checked this year in five other soils. The Atomic Energy Research Establishment at Harwell, in cooperation with his department, had for some years been carrying out long-term investigations designed to show the uptake of strontium 90, due to fallout from nuclear explosions, in the soil, vegetation, bones, and milk. Nine sampling sites had been chosen: 2 of them in Suffolk, 3 in Wales, and 1 each in Cambridge, Norfolk, Devon, and Durham. The sampling was done by the regional officers of his department and samples were taken of soil, grass, and animal bones—sheep bones in particular. Apart from those investigations, large quantities of milk had been taken for analysis from areas as far apart as Somerset and Northern Ireland. The results were being compared with the results of similar work in the United States, and in addition they had organised a supply of samples of soil, grass, and bones from Commonwealth countries

QUESTION TIME

Psychiatric Treatment for Prisoners

Sir LESLIE PLUMMER asked the Home Secretary how many prisoners sentenced to prison for sexual offences, and promised treatment for their abnormalities, in fact received such treatment —Mr J E SIMON replied Prisoners sentenced for sexual offences receive psychotherapy if they are found suitable for treatment and if the sentence is long enough to allow of it Particular attention is always paid to any recommendation by a court *In 1956, 60* men and boys sentenced for sexual offences received treatment by visiting psychotherapists, but I cannot say how many of these had been recommended for treatment by the court at the time of sentence Sir LESLIE PLUMMER Is it not clear that there is little validity in the statement made constantly by magistrates and judges to sexual offenders that when they go to prison they will receive the medical treatment which they should have for their abnormality ? Does not this mean that there must be a rapid extension of the very admirable psychiatric work now going on in Her Majesty's prisons ?—Mr SIMON We hope to extend that considerably when we get the new psychiatric institution at Grendon Underwood Mr ANTHONY GREENWOOD May we take it from the Under Secretary of State that he is not very happy about the facilities which are available ? Can he give a rather more definite idea to the House when he expects the facilities to be made adequate ?—Mr SIMON It would be very difficult to give a firm date for completion at Grendon Underwood, but a start is to be made this year

Use of Drugs

In the House of Lords the EARL of CRAVEN asked the Government whether they would consider, in the light of conditions arising out of Dr Adams's case, whether or not the time was appropriate for a review of the laws relating to the use of drugs for medical purposes —Lord STRATHCLYDE replied that the Government did not consider it appropriate to circumscribe the clinical freedom of doctors to treat their patients in accordance with their individual judgment except in so far as a doctor's authority to possess or prescribe dangerous drugs might be withdrawn, after conviction of an offence under the Dangerous Drugs Act The EARL of CRAVEN went on to ask if the Government were prepared to sanction euthanasia in any form. An answer to this question would give relief to a great many people in this country LORD STRATHCLYDE said that this was a completely different question, and he asked for notice before he answered it

Doctors for Colonial Territories

Mr DAVID JONES asked the Secretary of State for the Colonies to what extent there were still vacancies for doctors in the Colonial Territories, after the 300 applications which he received each year from qualified doctors already in the National Health Service in this country had been appointed to the Colonial Medical Service and allocated their posts —Mr A T LENNOX BOYD replied There are generally some 120 to 150 vacancies at any given time, recruitment being roughly balanced by normal wastage and, in some cases, by expansion in territorial establishments By no means all the 300 applicants take up appointments Mr JONES How many of the 300 applicants have their applications rejected ?—Mr LENNOX-BOYD Of the 300 applicants, approximately 45 are, on the average, rejected Of the remainder, about half withdraw their applications or decline offers of appointment Not all of these applicants are employed in the National Health Service

Mental Hospital Superintendents

Mr KENNETH ROBINSON asked the Minister of Health if he was aware of the increasing difficulty in obtaining suitable candidates for the post of physician superintendent in mental and *mental-deficiency* hospitals, owing to the lack of any financial inducement to compensate for the extra responsibilities, and whether he had considered the views of the Bradbeer and Guillebaud Committees on this subject —Mr VOSPER replied · I am aware of the difficulty and the views which have been expressed on the absence of inducement to consultants to take posts as medical superintendents at mental and mental deficiency hospitals The level of remuneration of these officers is within the terms of reference of the Royal Commission I do not feel able to comment further on it at present

In England Now

A Running Commentary by Peripatetic Correspondents

THOSE who switch off their light after getting into bed, knock their heads gently on the pillow 4, 6, or 8 times, and fall into a sound sleep until 4, 6, or 8 A M are envied by many But light sleepers who wake two or three times a night have learnt that even reduction of their sleep to five or six hours does not lead to ill health, and indeed may have compensations

When I put down my book, switch off my light, and turn on my side, my room seems very dark, but when I wake two or three hours later it is alive with a dim light This is caused by the projection, on floor, ceiling, and walls, of the distant street lights and the lights from neighbouring houses These are mostly dim, but after my sleep my eyes can appreciate them readily Sometimes a bright light suddenly appears and I know that one of my neighbours, too, is awake These lights always give me a sense of company during the night The large patch of sky which I see from my bed is rarely so dark that I cannot distinguish it from the house-tops, and it may be very light indeed when the moon is about on a clear night It also may be light when there are high clouds, which reflect the lights of London The planets, Jupiter, Mars, and, in the early morning, Venus, appear bright to my dark-attuned eyes A few months ago Jupiter and Mars were very close together I considered setting my alarm to see how close they would be the next night but decided to chance my luck I woke at the right time and found them so close that they seemed to touch, and the next night they had separated considerably I have also seen a planet nearly occulted by the moon in its last quarter When such sights are visible I lie in bed with my eyes open until I fall asleep

There are other pleasant sights and sounds On the Ides of March this year a blackbird, who prefers to nest among the chimney-pots instead of in the bushes on the other side of the house, began to sing at 5 36 A M Soon after dawn I may see the starlings flying up from their roosting-places in Trafalgar Square to their feeding-grounds in the country They differ in their habits from some of my colleagues who prefer to work in town and sleep in the country (These might be said to crawl there in comparison with the starlings) Later still come the pigeons and in the winter the gulls, which wheel above the house-tops until someone comes to feed them, when they sweep down in great circles Twice in twenty-two years I have seen a kestrel hovering over Great Portland Street (I have not had the good fortune of a colleague who once saw a peregrine falcon flying along the *Euston Road*)

All these sights and sounds add interest to the hours when I lie awake Provided I have had a pleasant day, recalling the events, say, of a game of golf, is a diversion But if the day has been difficult, my thoughts are sometimes too disturbing to let me sleep If so, I switch on my light and eat a digestive biscuit, which has the great merit that it crumbles easily against my almost toothless gums After various trials during the past forty-odd years I have decided that a drink of very hot water helps me more than any other drink I fill my 'Thermos' *on going to* bed and may eat and drink two or three times in the night As to reading, I may continue the book I was reading before I went to sleep, but if I am very restless I take a book which I can skim easily, dealing with "raw heads and bloody bones" *Kim* used to be a great standby and I could pick it up anywhere, but of late an old detective story may suffice Half an hour's reading is usually enough, but the process may have to be repeated more than once

I also use the night hours to thresh out my difficulties and often solve them When I *am writing* a paper I con the wording, or I think of a note such as this When I wake in the night I rarely feel *sleepy, but* at 8 A M I may be very sleepy *and loth to* get up When I was a busy house-physician I learnt to "go round" my wards, thinking *of the problems* of each patient, before I got up I still like to think over the problems of the day, while *still in bed*—though these, alas, are now chiefly committees To my mind those who sleep soundly miss many pleasant and interesting moments and the opportunity to solve some at least of their day-time problems. I have long ceased to envy them.

* * *

The other day, as I copied the names and addresses from the visiting-book in our surgery, I noticed that I accepted with sweet reasonableness a visit requested because of "spots," but "no better" or "getting giddy turns again" provoked irritation. My reactions made me wonder whether it might not be useful to insert in the appendix to all textbooks of medicine a Comparative Table of Disease and Doctor's Time. My own version would be something like this:

1 passport photo = 1 eye form = $^{1}/_{2}$ rubella.
2 rubella = 1 chickenpox.
3 chickenpox = 1 measles.
3 measles = 1 whooping cough.
17 whooping cough = 1 fat pink boy who's "had a cough for 3 years, doctor. Never sleeps a wink with it. Hasn't kept anything down for 2 years. Had whooping cough 8 times without the whoop, his last doctor said."
2 fat pink boys = 1 "only 94 and I don't seem to have any go in me, can't you give me a tonic?"
9 tired 94's = 1 chronic endogenous depression who has "seen most of the best psychiatrists in Europe and the last young specialist I saw said he couldn't give me the E.C.T. any stronger without stopping all the trains on the Inner Circle. But I'm no better and I'll pop round again tomorrow, doctor."

* * *

Restaurateurs' menus can be disturbing to the uninitiated, but my niece, aged 10, sees through them. Lately, she accompanied me to lunch at one of those small Belgravian restaurants where the décor is modern and the dishes recherché. She enjoyed an exotic preparation of "Filets de Sole à la Crème aux Champignons avec Sauce Mornay, les Petits Pois à la Nivernaise et les Pommes de Terre Dauphin." To her mother's inquiry later as to what she had had she replied without hesitation "fish and chips."

* * *

Away goes another illusion. That oft-quoted example of the perfect egalitarian community, the beehive, has let us down. It is indeed sad to learn that the famous waggle dance of the bee, far from being a conscious rallying effort for the good of the State, is but an elaboration of a primitive and innate reaction to a satisfactory meal.

An American biologist has shown that the common blowfly, a lone forager and confirmed individualist, can be made to perform a similar dance—with no audience—when its taste-organs are stimulated with a solution of sugar. This, he says, is simply an automatic reflex, whereby the fly hunts around hoping for more in the vicinity of the first find. Moreover, the complexity, duration, and extent of territory covered by the dance increases with the strength of the sugar solution, just as the vigour of the bees' dance is related to the concentration of the nectar collected. The bee apparently cannot even claim that its habit of regurgitating nectar from its honey sac on return to the hive is a desire to share with its fellows. The fly also regurgitates, and this we are told is in order to restimulate the taste-organs, and so reinforce the reflex and prolong the period and extent of the "food-searching" dance. Alas, it is for this purpose that bees, like the flies, gorge themselves to repletion when they chance on a food depot.

Thus the mystic "information" dance of the bee is but a delayed reponse to an effective taste stimulation, whose pattern and duration are controlled by the nasty habit of regurgitation of food from an overloaded stomach. According to the biologist, the complex and highly organised life of the hive has its origin in a primitive and wholly selfish individualistic rite.

* * *

Alas for the days when it was *de rigueur* for doctors to be properly dressed. The other day I went across to the ward to see a new patient. I was wearing a (slightly faded) black suit with striped trousers. The poor man was asleep when I approached, and got a terrible shock when he woke to find me standing by his bedside. He was sure I must be the undertaker.

Letters to the Editor

SENIOR REGISTRARS AND CONSULTANT APPOINTMENTS

SIR,—I write to support the letter of Dr. A. G. Freeman in your issue of April 27 and to congratulate you on the prominence which you gave to it. I find the Ministry's neglect of the senior registrars' problem as alarming for the future of medicine in this country as their refusal to negotiate in the matter of remuneration. When I stated, in a combined regional hospital board/board of governors medical committee the other day that there were too many senior registrar posts, a first-rate medical administrator retorted that the number had been fixed by the Ministry's statisticians—and, presumably, therefore we were intended to conclude that the number was right. From the figures in your table (April 13, p. 785) we may more correctly conclude that either the statisticians were wrong or they planned for an expansion of the consulting service which has not occurred.

I agree with Dr. Freeman that the appointment of senior registrars to non-teaching hospitals should be discontinued—at least in general medicine. It may be that in other specialties, such as general surgery and pathology, the non-teaching hospitals have more to offer the senior registrars. I am now convinced that in general medicine, although we may improve the experience of senior registrars, we do not promote their professional progress. Moreover, there is work waiting for consultants in non-teaching hospitals. In the group of hospitals which I serve we have an urgent need for another general physician and another general surgeon.

I do not agree with Dr. Freeman that these new consultants (again, at any rate in medicine) should be of assistant status. By the time a young physician has completed four years as senior registrar (doffing his cap and saying, "Sir, how splendid are your physicianly qualities and how unworthy am I, Sir, to take up your stethoscope") he should be independently fulfilling his own promise. This is the way of English medicine and it should not be lightly discarded.

Derby. DOUGLAS HUBBLE.

FATS AND DISEASE

SIR,—The question of the effects of dietary fats on serum cholesterol concentration, and the larger issue of the rôle of diet in the promotion of coronary heart disease, needs more facts and less argument. We do not propose to meet the letter from Dr. Kinsell and Dr. Sinclair in your issue of April 27 in a similar polemic defending one point of view and attacking all others, but your readers may be served by providing a few facts.

In the first place it is simply not true that in our experiments[1] "the actual qualitative and quantitative fatty-acid composition of the oils was completely unknown." The sardine oil used, prepared from *Sardinops cærulea*, the California sardine, was found to have an iodine value of 188 and saponification value of 174. We did not attempt a detailed analysis of the extremely complex lipids in this fish oil but for these purposes were content with the finding that this oil was, indeed, very highly unsaturated as is typical of the fish oils. And we noted that such fish oils have been universally found to be low in linoleic acid and to contain only very small amounts of arachidonic acid. Aliquots of the other oils were stored in full containers at –20°C and at the end of the experiments these were analysed blind by the research division of Procter & Gamble Co., with the following results for corn and sunflower seed oils respectively:

Iodine value: 123 and 140. Percentages of the fatty acids: saturated, 15·8 and 10·3; monoene, 26·2 and 18·2; diene, 56·6 and 70·8; triene, 0·7 and 0·1. Trans acids amounted to 0 7% and 1 3% respectively, while conjugated dienes were less than 0·6% in these oils

---

[1] Keys, A., Anderson, J. T., Grande, F. *Lancet*, Jan. 12, 1957, p. 66.

Kinsell and Sinclair state that the efficiency of absorption of the oils in our experiments was "apparently unknown" We are unaware of any evidence that fresh oils such as we used are not well absorbed by man, and we do know that their ingestion by our subjects was not productive of any steatorrhœa or change in calorie equilibrium Since the test oils provided more than a fourth of the total calories in the diet, any significant failure of absorption would have caused a loss of body-weight

It may be that changes of 9 3 and 20 2 mg of cholesterol per 100 ml of serum "would be regarded as being within the range of spontaneous fluctuation" in the laboratories of Kinsell and Sinclair They are unaccustomed to studying groups of men in controlled cross-over experiments and so apparently pay no attention to statistical analyses or the significance of mean changes of 14 and 12 men, respectively, that are 3 3 and 5 4 times the standard error Incidentally, these changes are in the *opposite* direction to those expected if conformity existed with the hypothesis that either linoleic-acid content or degree of unsaturation were the controlling factor in such comparisons

Kinsell and Sinclair ask about comparison of olive oil with cotton-seed oil Such comparisons with 16 men subsisting for four weeks on each oil in a strictly controlled cross-over experiment, and with 12 men in a similar experiment with two-week cross-over periods, are provided in a paper currently in the press on the Effects of Different Food Fats on Serum Cholesterol Concentration in Man [2] No significant differences were found

We have been conducting experiments with safflower oil which is remarkable for its very high content of linoleic acid (70–80%) and correspondingly high iodine value The effect of safflower oil on serum-cholesterol in man is less than that of corn oil An interesting demonstration of this fact was made recently by the University of Minnesota Medical School class in physiological chemistry The serum-cholesterol response to the daily ingestion of 57 g of fat was studied in 141 students This admirable class exercise, under the guidance of Prof W D Armstrong, which is now ready for publication, showed lower serum-cholesterol levels on corn oil than on safflower oil, both by the students' analyses and by our own which were made ' blind" The oils used, analysed by Dr R T Holman of the Hormel Research Institute, proved to have, respectively, iodine values of 126 7 and 144 2, with linoleic acid comprising 57 5 % and 72 0% of the fats.

We should call attention, also, to the recent study of Beveridge, Connell, and Mayer,[3] from which they conclude, "The results demonstrated unequivocally that the plasma cholesterol depressant effect of corn oil depends to a large extent upon its sterol content"

Kinsell and Sinclair state "It is known that the feeding of a synthetic triglyceride containing unsaturated fatty acid is associated with a major decrease in serum-cholesterol as compared with the level existing during the ingestion of an equal amount of vegetable fat essentially devoid of unsaturated fatty acid," and they cite as evidence a letter to the editor of the *American Journal of Clinical Nutrition* [4] We should have thought it wiser to attempt to forget this little note but, since it is again seriously offered as evidence, it must be examined

The synthetic triglyceride was stated to have the following fatty-acid composition oleic acid, 74%, palmitic acid, 19%, stearic acid, 5%, linoleic acid, 2% Approximately 100 g of this fat was ingested daily by a single patient and "a prompt and profound decrease in plasma cholesterol occurred" If we were to credit this report, we must conclude that the linoleic-acid content of this fat could explain no part of the reported effect, since the synthetic triglyceride they used is as near to being devoid of linoleic acid as any natural fat or oil we know about The equivalent fatty-acid composition would be approached by beef tallow plus a little olive oil Natural (unhydrogenated) coconut oil contains about 2% linoleic acid while butter-fat and lard usually contain about twice and four or five times as much respectively If the "essential" fatty acid was the effective agent, butter-fat should have the same effect only much more so But, since this synthetic material was reported to cause a fall of around 100 mg of total cholesterol per 100 ml, to a value between 100 and 150 mg per 100 ml, perhaps it contained some remarkable factor not indicated by the fatty acid composition, and Kinsell and colleagues should make it available to the pharmaceutical trade

We should have thought it was clear enough in our letter of April 13 that we do not deny an important rôle of degree of fatty-acid saturation in the effect of dietary fats on serum-cholesterol Our evidence is that the saturated fats have a powerful cholesterol-raising effect, that the mono ethenoids (or more specifically, oleic acid) cannot be very influential, and that the poly-ethenoids have a cholesterol depressing effect which is considerably less powerful, per gramme, than the opposing action of the saturated fats Further, our evidence indicates that corn oil has an effect additional to that which may be ascribed to its fatty-acid content As of this date, we are unaware of any significant published data with which these conclusions are inconsistent

PULMONARY COLLAPSE IN CHILDREN

SIR,—Your excellent annotation [1] was very stimulating. James et al [2] may indeed be congratulated on their presentation of the natural history of pulmonary collapse in childhood In their study of 5000 consecutive chest radiographs in children, 854 patients were diagnosed as having pulmonary collapse The follow-up study in 472 patients was completed and analysed ætiologically, but no mention is made of cystic fibrosis of the pancreas except for a passing reference in the miscellaneous group of 29 children—9 cases, all fatal

Our experience in the New England area shows that pulmonary collapse, lobar and segmental, transient and persistent, is not uncommonly a feature of cystic fibrosis of the pancreas The incidence of this disease is about 1 in 600 children, it forms 3–6% of all admissions in the large pædiatric hospitals, and causes about 5% of hospital deaths In this Center a study of some 600 cases of mucoviscidosis confirms the common association with pulmonary atelectasis and bronchiectasis (5–15%)

Of additional interest in the study by James et al is the anatomical distribution of lobar and segmental collapse As a whole, the right lung had a greater incidence of collapsed segments than the left, but of the lobes, the left lower had the greatest incidence and the right middle the next greatest Their explanation that collapse is due to the left lower lobe bronchus being obstructed by aspirated and secreted mucopus, and the right middle lobe bronchus becoming occluded by enlarged hilar glands with or without erosion may be true in many cases Di Sant Agnese's[3] and our observations, however, both suggest that the prevalence of collapse in the right lung (mostly right middle lobe) in many patients with cystic fibrosis of the pancreas is due to endobronchial obstruction with viscid, highly tenacious, bronchial secretion Our experience points to the fact that, for instance, many patients treated for asthma or some others suspected to have pulmonary tuberculosis have been proven in this Center to have cystic fibrosis of the pancreas with or without pancreatic enzyme deficiency

We have also studied 6 children with mucoviscidosis [4] having predominant respiratory difficulties in whom lobectomy was performed for persistent lobar or segmental collapse or bronchiectasis or both In 4 of them the diagnosis was made preoperatively, but in the other 2, aged 3 years and 8 years, the diagnosis was not made until six and twenty months respectively after operation, when the children were referred to the

clinic In all 6 children the histopathological changes in the resected pulmonary segments were typical of or compatible with cystic fibrosis The recent introduction of a diagnostic chloride-imprint test [5] has made it possible to confirm this disease within a matter of minutes, and a large number of children can be screened within a short period

Pulmonary atelectasis may indicate cystic fibrosis of the pancreas, and *it is important not to overlook the* association Further, mucoviscidosis may also be responsible for occasional localised bronchiectatic changes or collapse and therefore should be considered in every case where a lobectomy is suggested

SALMONELLÆ IN REPTILES

SIR,—I refer to your annotation of March 23 In Cape Town there is a very high summer incidence of gastro-enteritis We have many flies but no reptiles in the urban area A colleague who had worked in Ibadan remarked recently that, despite the primitive sanitation, flies there were scarce and the incidence of gastro-enteritis was very low It was suggested that the abundance of lizards in that hot climate kept down the fly population, which was a prominent vector of salmonellæ If that is so, this observation suggests that reptilian excreta are not so dangerous as human

UTERINE ELECTROLYTES IN PREGNANCY AND LABOUR

SIR,—We were delighted to read the letter of Dr Hawkins and Professor Nixon (April 20) with its valuable criticism of our short communication and confirmation of the main clinical point raised—namely, that uterine inertia can be associated with a reduction of potassium in the myometrium

We quite agree that part of the "normal labour" group may have contained a number of cases of trial of labour which had gone on long enough to be on the borderline of uterine inertia, or which would have been uterine inertia had they been left This selection is in part necessitated by the very conservative approach to cæsarean section in Czechoslovakia There is a far smaller incidence than in England, and an elective cæsarean section is quite rare, except for cases of placenta prævia diagnosed beforehand, which is itself a rare occurrence Since a trial of labour is the rule, this limits the possibilities of selecting patients at various stages of labour, and since we are unwilling to biopsy a healthy uterus in a young woman of childbearing age to the extent required for muscle analysis, our selection of non-pregnant controls was also to some degree compromised—a necessary compromise we feel

Hormonal explanations are very much the vogue in dealing with electrolyte changes these days, but it is perhaps a mistake to neglect other factors Acidosis per se can lead to a loss of K from muscle cells, and a metabolic acidosis is often found during labour, particularly after the prolonged labour of uterine inertia Drs Vedra, Hoder, and Štenbera (to be published) in Prague have been following blood lactic acid levels and other effects of acidosis on carbohydrate metabolism during labour, and have found significant effects Moreover, the factor of local anoxia, which would lead to similar tissue changes, cannot be ruled out at present

We would ourselves be very hesitant about drawing conclusions from either the determined level of K concentration in the serum, or the calculated level of K concentration in myometrial, or any other, cells The correlation of serum K with cellular levels is seldom reliable except in extreme cases, and since one does not really know how much cell K or H_2O is bound, it is not very meaningful at present to speak of concentrations in the intracellular fluid under such conditions

We would finally broach the point that the borderline between a "physiological" K loss from cells and a "deficiency" is not necessarily an easy one to recognise, particularly since the latter word is a more general clinical term which should include some data on the total K balance in more quantitatively significant tissues than myometrium The word "physiological," when used in a clinical situation, should, we feel, connote whether a given process is advantageous to the patient or not, and we would ask whether any loss of K from the myometrium, whether covered by the term "physiological" or "deficiency," is advantageous or disadvantageous to the patient in labour

Prague, Czechoslovakia

R L CORT
J H CORT

ON THE UTILITY OF THE WORD *FÆX*

SIR,—There are, in the vernacular, two words which approximate in meaning to the commonly used *fæces* One is used exclusively as a substantive to denote a discrete mass of fæcal matter, the other as a verb or noun Their persistence through the centuries attests as well to their utilitarian as to their scatological value Physicians need an acceptable word which will permit the greater flexibility inherent in our Anglo Saxon heritage *Stool* does not meet this need, it lacks sharp definition and is employed variously—to go to stool, pass a stool, stool of such and such measurements, formed stool, watery stool, &c *Fæces*, a collective noun in plural form, also lacks precise meaning

It is the singular which we require, this will permit us to say, in one word, that unit of a formed stool delimited by two successive anal sphincteric contractions *Harper's Latin Dictionary* (1907, p 720) gives *fæx, fæcis* as this singular The diphthong suggests that the word be pronounced *feex* Some clumsy circumlocutions might be avoided by incorporating *fæx* into our medical vocabulary

VINCENT J DERBES

THE LIVER IN HÆMOCHROMATOSIS

SIR,—In your leading article (Feb 23), you draw the conclusion that African studies support the view that the influence which leads to cirrhosis also leads to increased absorption of iron The facts available do not seem to support this view

Most abnormal livers in the South African Bantu, in whom siderosis is common, fall into two categories

(*a*) *Livers with a severe coarse cirrhosis*, the histological features of which (in most cases) suggest post necrotic origin [1] This type of cirrhosis is unrelated to the presence of siderosis

(*b*) *Livers with a fine portal fibrosis*, which develops into a true septal cirrhosis only occasionally The relationship of fibrosis to siderosis in this group is striking, and in some cases there is evidence of liver cell degeneration associated with hæmosiderin deposition

It is thus possible that, in the Bantu liver, iron pigment deposition may not be benign Further, the histological picture also suggests fibrosis secondary to iron pigment deposition, which is in contrast to experimental work, when, however, iron is almost invariably deposited in a healthy liver In these cases the iron storage pattern in the body is different from that seen in classical hæmochromatosis, and diabetes mellitus is not a feature

That the mechanism of iron absorption is abnormal in the African has yet to be proven Walker and Arvidsson [2] have brought forward considerable evidence that it is unnecessary to postulate such an abnormality to explain the widespread visceral siderosis found in the Bantu of

---

[5] Shwachman, H Gahm N *New Engl J Med* 1956 255, 999

[1] Higginson J Grobbelaar B G, Walker, A R P *Amer J Path* 1957 33 29

[2] Walker A. R P Arvidsson, U B *Trans R Soc trop Med Hyg* 1953, 47 536

Southern Africa Moreover, Bothwell et al [3] were unable to demonstrate abnormal iron absorption in 4 patients with Bantu siderosis

The significance of diet in Bantu siderosis has yet to be established While it is true that diet has been shown to influence the absorption of iron in animals, this seems to be because conditions inside the bowel render the iron less easily available to the mucosa for absorption rather than because the mucosal barrier is damaged In rats fed a diet of maize, porridge, and sour milk supplemented by iron, I was unable to demonstrate increased iron deposition as compared to a control group on a stock diet

I would therefore subscribe to the view that as yet it cannot be stated that the factors causing siderosis and cirrhosis in the Bantu patient are the same, or that dietary pattern (apart from excessive iron intake) is a major factor in African siderosis and liver cirrhosis in this region

VACCINATION AND THE EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—Your editorial of April 20 on formolised polio myelitis vaccine says "when children are vaccinated first, the young parents may for a time be more commonly exposed to the risk of paralytic infection as a result of inapparent infection by virulent virus in their children" This statement has already caused anxiety, which may be unjustified to parents about to have their children vaccinated With a properly prepared and tested vaccine no live virus is being introduced into the community which was not already circulating naturally The supposed risk to parents can thus arise only because they are being exposed to infection which they would avoid if they were able to recognise the illness in their children You cite evidence that in an unvaccinated population there may be 32–496 subclinical infections to every clinical case, so that at best it is possible for anybody to recognise no more than 3% of those who expose him to risk of infection

It is almost impossible to distinguish non-paralytic poliomyelitis from other forms of aseptic meningitis so quickly that the patient can be isolated before others are exposed to risk, while the appearance of paralysis which makes the diagnosis simpler is often too late to serve as a warning The recent studies of Littell and Smith [4] and of Spicer and McDonald [5] underline this by the demonstration that multiple cases in families are usually so close in time of onset that quarantine measures taken after the appearance of the first case would have little value It seems that vaccination might conceal a very small proportion of the infections which expose patients to risk, but that in any case the recognition of an infection in a child gives the parent very little opportunity of protecting himself

You further state "we do not know whether vaccination of children by existing methods will protect them until they have reached the young adult age, at which infection is more likely to cause severe paralytic disease" In this formolised poliomyelitis vaccine may well be no different from other immunising agents It is not apparent why prolonged immunity could not be as readily obtained by reinforcing doses of a formolised vaccine rather than by the use of live attenuated virus Indeed, the international requirements for vaccination against smallpox or with yellow-fever vaccine would seem to imply that the live virus vaccines do not always produce life long immunity Furthermore, the recent studies in Belfast suggest that with the use of live attenuated virus there may well be a risk to the parents of vaccinated children

London School of Hygiene and Tropical Medicine, W C 1

J KNOWELDEN

CLINICAL COMPARISON OF DIAMORPHINE AND PHOLCODINE

SIR,—In your issue of April 27 Dr Snell and Dr. Armitage introduced a very useful method of sequential analysis for the evaluation of clinical trials

I must, however, disagree with the title of the paper, "Clinical Comparison of Diamorphine and Pholcodine as Cough Suppressants," since the authors have compared 'Lipect' with diamorphine linctus *B.P C* the former containing, inter alia, antazoline and liquid extract of ipecacuanha, and the latter oxymel, all of which are far from being inactive ingredients

Dr Snell and Dr Armitage show that

(*a*) Lipect is superior to the placebo
(*b*) the placebo is inferior to diamorphine linctus , *but*
(*c*) "at the 5% level of significance there was no evidence of difference between the heroin and pholcodine preparations"

I submit that the latter conclusion really refers to diamorphine linctus and lipect and that, had the test been carried out with only one of each of the drugs under test in an inert base containing, perhaps, some flavour to mask the taste of pholcodine, then a truer evaluation of the effectiveness of the two drugs would be obtained

This is especially true in this case since the difference is only borderline at the 5% level and such a standardisation of vehicle for the drugs (and placebo) might tip the balance in favour of one or other of the drugs

JAMES C PARKINSON

GOVERNMENT AND PROFESSION

SIR—Dr McCallum (May 4) seems to take great exception to letter of "Blackleg" (April 27), but are there not several good points in it—particularly the last paragraph about negotiating terms of service instead of talking about principles ?

I wonder if Dr McCallum remembers a little booklet issued by the public relations department of the British Medical Association in 1948 ? It was called *The Doctors' Case* On p 6 is the following "The dispute is not about money The government has treated the profession fairly enough in its arrangements for deciding what doctors should be paid The issue is a matter of *principle*"

Dr McCallum says that to do everything by postal ballot would increase the subscription by at least one guinea Does he forget that, before the last election for the G M C, doctors were circularised with documents asking for the support of certain candidates ? This was done through the B M.A organisation but I have not heard yet that the action was as expensive as he suggests

Worthing

HAROLD LEESON

SIR,—Nothing could be more alarming than Dr Grant's suggestions (April 27) for revising the system of payments to practitioners

Rewards given to doctors for keeping their prescribing costs low, for reducing the certified days off work of patients on their lists, and for reducing the number of patients sent to hospital would mean quite simply, that a doctor would not be rewarded for good doctoring but for his part in promoting public economy Heaven knows what kind of desperate cut pricing competition this would lead us to

Apart from the objections I have mentioned, Dr Grant's system smacks too much of good marks for the good boys with yet more work for the bureaucrats and yet more control Better by far the present abuse, which has at least this to recommend it—that the patients do not suffer from cheese-paring physicians keen as governesses to pack them off to work after dispensing thrifty therapy Nor is their admission to hospital delayed in order to provide points for the good boy

SURGEON'S "PRIVILEGE"

SIR,—It is with indignation that I hear that the legal question of surgeons' meals in hospital (referred to in Mr Capener's letter last week) has ever been raised

How mean can hospital administrators become? If they are really interested in the saving of a few shillings a week in hospital expenditure, they should first assess the cost and necessity of their own tea-breaks and luncheons during their short and regular working hours

It is the surgeon who sacrifices his night's rest, gastric mucosa, and blood-pressure in the interest of the patient In Mr Hamilton Bailey's words "To a patient stricken with a catastrophe necessitating an operation, the physical fitness and mental alertness of his surgeon are almost as important as the surgeon's training and experience" For this reason alone, the surgeon needs adequate nourishment between operating sessions

Who would grudge the hardworking surgeon his occasional frugal hospital meal? Certainly not the patient, or the nursing staff

Royal Aberdeen Hospital for
Sick Children, Aberdeen **BARBARA JUDGE**

INSULIN TREATMENT OF SCHIZOPHRENIA

SIR,—May I attempt a further defence of what appears to me an irrational but well-patronised remedy now being condemned on very slender evidence? It was unwise to get trapped by the irrelevant yardstick of discharge, but at least I seem to have been in the company of Dr Ackner and his colleagues

Consider their result in terms of clinical states Clearly there was no difference in recovery-rate in the insulin and control groups (9/24 and 10/25), but this means nothing unless the precision of this apparent absence of difference is considered Perhaps the best estimator in such a trial is the percentage difference between the recovery-rate in the two groups Let us consider a result of the form

	Insulin	*Control*
Recovered	a	b
Not recovered	c	d

This estimator will be $\left\{\left(\frac{a}{a+c}-\frac{b}{b+d}\right)\times 100\right\}$ % and will have a standard error of $\left\{\left(\sqrt{\frac{ac}{(a+c)^3}+\frac{bd}{(b+d)^3}}\right)\times 100\right\}$ %

In the trial considered this standard error is about 14%, so that the only statistical inference that can be made with reasonable safety is that insulin therapy would be unlikely to benefit more than 20% of patients

It would be interesting if exponents of this treatment would give their views on what percentage benefit should be expected Suppose it were 10% (and this would be a most important contribution to the therapy of a common disorder), then such a trial could reject this claim with reasonable provisional safety, on statistical grounds, only if the precision of their estimate were such that it had a standard error of less than 6% This would require well over 200 cases

With such low precision available from such an analysis of such a trial it seemed reasonable to question the assumption that more was gained than lost by leaving the bedside I did not intend to question the randomising of therapy

As the function $\left(\sqrt{\frac{ac}{(a+c)^3}+\frac{bd}{(b+d)^3}}\right)\times 100$ will usually approximate to $\frac{100}{\sqrt{N}}$ in a blind trial of N cases in which a single response, such as recovery, occurs in from one-third to two thirds of cases, this sets an absolute limit to the precision of a debunking trial of this type

Conventionally, using a one tail test at the usual level of significance, a claim that a worthless but harmless remedy has a benefit of p% will usually take more than $\left(\frac{165}{p}\right)^2$ cases to contradict on statistical grounds If a 5% benefit is regarded as of practical importance (and who would forgo a 1-in-20 chance of recovery?) exponents of therapies need not be intimidated if such trials show "no statistically significant differences" unless the numbers exceed at least a thousand

Birmingham **J H EDWARDS**

RELEASE OF HISTAMINE IN URTICARIA PIGMENTOSA

SIR,—The preliminary communication by Dr Hamrin from Lund University, in your issue of April 27, is most interesting Although patients with urticaria pigmentosa do not show intolerance to salicylates, those with chronic urticaria not infrequently do so There are genuine cases of urticaria and associated reactions which are manifestations of true allergic sensitivity to salicylates Their reaction occurs only in response to these drugs, and they would seem to have specific antibodies

But apart from such instances, there are patients with chronic urticaria who are made worse by taking salicylates, and who improve but do not clear up when the drug is stopped Their reaction does not appear to be a specific allergy That salicylate may act as a histamine liberator in such cases (as suggested by Dr Hamrin), and so aggravate the urticaria, would be an acceptable explanation

TONSILLECTOMY

SIR,—Your annotation of April 20 was stimulated by my "Tonsils and Adenoids Evaluation of Removal in 50 Doctors' Children,"[1] and it seems *a little unfair*, in view of my carefully worded title, to complain that I did not have a control series or say how many doctors' children I had decided not to operate upon in the same period of time My belief that the operation was of great benefit for the conditions for which I undertook it was confirmed by my study of the results in these 50 doctors' children, and I would have felt a little unhappy and certainly not very helpful to my colleagues if I had refused to operate upon some of their children in order to use them as controls Many experienced general practitioners and pædiatric physicians believe as I do, and I wonder if you are justified in stating that "it is fairly well known that introduction of controls shows that the operation makes no impressive difference" That statement is based on a small series which you suggested[2] would have shown the same result whatever the number Comparable controls are very difficult to come by, and the numbers would have to be very large to equal out the variations If you had applied the same kindly thought, exercising unbiased editorial outlook, to my small series, I think you would have been getting nearer the truth

London, W 1 JAMES CROOKS

HAZARDS OF EPOXIDE RESINS

SIR,—Your annotation of April 20 in my opinion calls for comment A distinction should be drawn between the resin and the catalyst, as well as the finished polymerised resin product My experience with the amine catalysts over the past 9 years has shown that the amines are the most dangerous hazard and sensitisation to any one is liable to cause further sensitisation to others Boas Traube et al[3] and Dernehl[4] reported on the amines as skin poisons long enough ago to warn of the need for caution There is also the further problem of dangers arising from the partially polymerised final compound, which if drilled, sawn, or otherwise worked may give off a fine dust which is also a marked irritant when inhaled[5]

You state that "manufacturers of resins and hardeners are well aware of the hazards involved" If they are, then *it* appears to me that they could have done much more to prevent the trouble They have not been outstandingly cooperative, in fact it is known that one company in U S A had carried out considerable research on the toxicity of the glycidyl ethers, closely related *compounds*, and published its results in 1954 It is also known that another large producer in Europe has been investigating these compounds for some years without publishing data In spite of this, the information on prevention has not been passed on in a satisfactory manner to users It would *appear that question* of international patents complicates the *publishing of complete* data of the processes I am indebted to Mr W Whitby for clarifying the position he informs me that "in the U S the situation is quite different from that on the Continent of Europe because the U S Courts have forced the companies under the anti-trust laws, and also under the rulings re the Devoe and Raynolds patents, to form a patent pool This has *prevented* to some extent the hold that "X" has on some patent operations in Europe I discovered these various things in attempting to get information at an early date"

As far as prevention is concerned, *I do not* permit the use of gloves in the factories under my supervision The sticky compounds cause the fingers of the gloves to adhere to each other They dry and get hard, reducing manual dexterity considerably An adequate barrier-cream, good washing facilities, a "no-touch" technique, and reasonable engineering application have been adequate to prevent any cases The recent introduction of a resin-removing cream has eased the situation considerably This will remove even the hardened resin from the skin without damage to the epithelium

Unfortunately epoxide resins and amine catalysts are used in many small factories where no medical facilities are available and where the knowledge of protective *methods is practically non* existent

London N 5 Senior medical officer A C Cossor Limited

THIRTY-MINUTE SCREENING TEST FOR PHÆOCHROMOCYTOMA

SIR,—I wish to add my support to Dr Frazer's remarks (May 4) on this test

With this method, I too have recovered only about 30% of both noradrenaline and adrenaline added to urine, using either B D H alumina (prepared as described in the original paper) or Woelm acid alumina (L Light & Co Ltd)

Increasing the amount of alumina and eluting several times with acid did not increase the recoveries recoveries of catecholamines added to water were, however, quantitative

Pekkarinen[1] notes that there is a substance present in the eluate from urine which inhibits fluorescence This effect is neutralised by using high dilutions, but this requires a sensitive fluorimeter for measurement

Like Dr Frazer, I seem to be a slow worker requiring almost two hours for one estimation

Royal Sussex County Hospital
Brighton 7 CLIFFORD RILEY

SIR,—In reply to Dr Frazer's comments I should like to give the following information which, to save space, I omitted from the original paper

(1) In preliminary experiments using a fixed volume (200 ml) of urine it was found that recovery of added catechols varied greatly (as judged by fluorescences obtained), the recovery from more concentrated urines usually being obviously lower By using an aliquot ($^1/_{10}$) of a 24-hour collection diluted to 200 ml these variations in recovery were greatly reduced Since the standard is prepared always from a pooled urine specimen we are concerned only with variations in recovery *from urine* and comparison with pure noradrenaline standard is irrelevant

(2) Although visual comparison of fluorescence is sometimes difficult, the specificity of adsorption on aluminium oxide at pH 8 5 is such that few interfering substances are present and urines having 2 µg difference in added noradrenaline (equivalent to 20 µg per 24 hours) can be distinguished In one or two cases a blue fluorescence was seen and on these occasions or whenever a comparatively high fluorescence was obtained, the test was repeated including recovery estimations on the urine being tested

(3) The aluminium oxide used (Merck) was dried, after washing and filtering by suction, by spreading on large sheets of filter paper and leaving overnight in a warm room followed by heating in an oven at 100°C for one hour As the same batch of aluminium oxide (kept in a *stoppered bottle*) was always used for unknowns and corresponding standards, variations *in* adsorptive properties were of no consequence

The results given for urines tested were intended to represent only very approximately the levels of catechols present, the primary object of the test is to detect amounts in excess of 180 µg per 24 hours That it is capable of doing so can readily be shown by a few tests on normal urines with and without added noradrenaline

CLINICAL THERMOMETERS

SIR,—Having been the victim of a pyrexial illness, I have been wondering why the so called half-minute clinical thermometer requires at least two minutes to record a correct reading, and why in domiciliary practice no adequate means of sterilisation has been devised to prevent the possibility of cross-infection

London W 2 F WIDLAKE

DEFINITION OF MENTAL DEFICIENCY

SIR,—The modern medical concept of mental deficiency is of social incapacity due to incompleteness of development of mind

Thus, we find detained on order under the Mental Deficiency Acts not only the obviously idiot, imbecile, and feebleminded, but patients who might equally well be regarded as aggressive psychopaths, habitual criminals, or merely members of the "social problem" group Whatever our professional concept may be, there is no doubt that in the public's mind mental deficiency is identified with low I Q I feel it is the interpretation of this concept to include a wide range of I Q s which gives rise to the recurring allegations of wrongful certification

It was repeatedly put to the Royal Commission on the Law relating to Mental Illness and Mental Deficiency that high grade patients should not be cared for in the same hospital as lower grade patients, and there is no doubt they resent being classified in the same way as patients in whom the defect is more obvious

Those of us concerned with the care of mental defectives have been at some pains in the past to avoid the acceptance of the I Q as a basis for diagnosing mental defect However, it seems to me that it would clarify the present position and ultimately improve the therapeutic possibilities if we limited the term "mental defect" to a condition of social incapacity with low I Q (below 70) and treated as a separate problem social incapacity with higher I Q s

Patients falling into the latter group are often more in need of psychotherapy than of the type of training given in most mental-deficiency hospitals, and if they are considered to require institutional care, I suggest this should be given outside the provisions of the Mental Deficiency Acts At present there is no other legislation to cover this group, apart from voluntary admission to a mental hospital Most of these patients are not suitable for admission to the ordinary mental hospital, and there seems to be a need for separate accommodation for them Where their voluntary admission was not considered appropriate, their admission could be obtained on magistrates' order after the presentation of a petition as under section 6 of the Mental Deficiency Act, such legislation should be incorporated in the Mental Treatment Acts

I am aware that there will always be borderline cases, which will give rise to difficulty, but the sooner we stop calling the socially inadequate group with "normal" I Q "mental defectives," the sooner we shall remove a powerful source of resentment among these patients, the greater will be our chance of obtaining their coöperation in psychotherapy, and the less frequently will we be accused of wrongful certification

Bristol W ALAN HEATON WARD

SERUM-CYANOCOBALAMIN LEVEL IN CHRONIC INTESTINAL DISORDERS

SIR,—Dr Meynell and his colleagues (May 4) fail to do justice to the pioneer work of Dr G I M Ross and Dr D L Mollin, at the Postgraduate Medical School of London, on the assay of vitamin B_{12} in human serum

Ross[1] was the first to adopt a microbiological assay of vitamin B_{12} (that of Hutner and co workers[2]) to the quantitative measurement of the vitamin in serum and other body-fluids, and to demonstrate that the serum B_{12} concentration was unusually low in pernicious anæmia In 1954, Mollin and Ross[3] gave details of serum assays in a variety of gastro intestinal types of megaloblastic anæmia included in this report were data obtained from 33 patients with idiopathic steatorrhœa, 13 of whom had low serum B_{12} concentrations

Neither of these papers are mentioned by Dr Meynell and his colleagues

Postgraduate Medical School of London J V DACIE

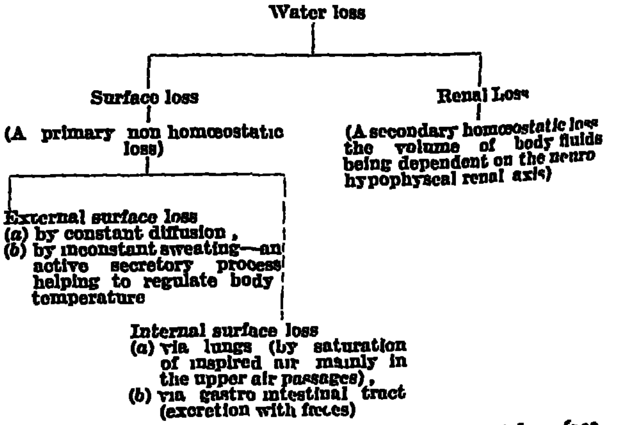
WATER-LOSS FROM THE BODY

SIR,—There is not, to my knowledge, any real justification for describing the combined water loss from skin and lungs as "insensible loss" Thus, Le Quesne in his excellent monograph[4] says

> Unfortunately there is no satisfactory term to describe this loss [entire losses from skin and lungs] There are cogent objections to the use of the three most obvious terms—namely "insensible loss," "inevitable loss," and "extrarenal loss"

The chief drawback of such terms is that they describe qualities of water loss which do not serve to illuminate our understanding of either their source or their nature It is perhaps impossible to coin an ideally all inclusive "blanket" term, but I suggest "surface loss" to replace the one most commonly used—"insensible loss"

At first glance this term might seem *as vague as* "extrarenal loss," but in the context of the classification given below I hope it may prove more accurate



Water loss
Surface loss
(A primary non homœostatic loss)
Renal Loss
(A secondary homœostatic loss the volume of body fluids being dependent on the neuro hypophyseal renal axis)
External surface loss
(a) by constant diffusion ,
(b) by inconstant sweating—an active secretory process helping to regulate body temperature
Internal surface loss
(a) via lungs (by saturation of inspired air mainly in the upper air passages) ,
(b) via gastro intestinal tract (excretion with fæces)

I use the word "surface" to express the *total* surface presented by *the body to* its environment, which is therefore external (mainly as skin) *and* internal (mainly as the lining of the gastro intestinal *tract* and lungs) The term "homœostatic" in the above classification is used in the specific sense of the body-fluid homœostasis and does not include thermal homœostasis A very small amount of water is lost via the secretions of the exocrine glands of lactation, salivation, lacrimation, and via the genital secretions This loss could be included in the surface loss

SUBUNGUAL HÆMATOMA

SIR,—May I add a simple method for the relief of pain in a subungual hæmatoma, which I have been practising for years? It is very quick and effective

An old pocket sized surgical knife with a very narrow blade is used The point has lost its sharpness and is more round The knife is placed perpendicularly on the nail, with its point resting over the centre of the hæmatoma It is rotated there and back with the thumb and index-finger exerting only light pressure After a few movements the nail is painlessly penetrated and a few drops of dark and thick blood appear These are wiped away and after a few more rotations with the knife all the blood of the hæmatoma is evacuated The hole made in the nail in this way allows an easy escape of the thick blood

Using a needle, safety-pin, or other similar pointed instrument, as advocated by some, is bound to cause pain, because it has to penetrate the nail enough before the blood begins to escape, the sharp point meanwhile pricking the sensitive subungual tissue Using the old knife without a sharp point makes the hole in the nail larger before touching the subungual tissue

London S E 25
A FRY

Obituary

GEORGE AUGUSTUS AUDEN

M.A , M D Camb , Ph D Birm , F R C.P , D.P H

Dr Auden, who died on May 3 at the age of 84, was Birmingham's first school medical officer When he was appointed in 1908 he was a consulting physician rather than a specialist in public health, but he was drawn to this comparatively new form of medical practice by his interest in education and children His wisdom as a physician was matched by his learning as a scholar and antiquarian, and in letters to our columns he would quote from Sanskrit writings as easily as from the *Saga of St Olav*

He was the son of the Rev John Auden, of Horninglow, Burton-on-Trent, and he was educated at Repton and Christ's College, Cambridge, where he was a Porteous medallist After taking a first-class in the natural sciences tripos in 1893 he continued his medical studies at St Bartholomew's Hospital where he won the Kirkes scholarship and medal and the Lawrence scholarship and medal Having qualified in 1896 he held house-appointments in London at Barts and at the General Lying-in Hospital Later he settled in practice in York and was appointed physician to the York County Hospital In 1908 his interest in education led him to apply for the new post of school medical officer at Birmingham There was strong competition for the appointment, but the committee was impressed by Auden s work for children at York County Hospital and his membership of the school board and education committee of the city

At first the work of his new department had to be directed to relieve disease, but even in those early days he showed that he was far sighted and broad-minded In his first annual report he stressed the need for psychological help in "the many problems which beset educational effort" Much later his own ability to assess the psychological needs of children was recognised by his appointment as honorary psychiatrist to the Birmingham Children's Hospital

During the 1914–18 war his work at Birmingham was interrupted by his service with the R.A M C in Egypt Gallipoli, and France On his return he quickly took up the threads of his growing department He was also "sanitary adviser" to the governors of Rugby School and demonstrator and later lecturer in public health in the University of Birmingham When he was elected F R C P in 1919 he was one of the first school medical officers to be admitted to the fellowship Meanwhile the emphasis of the work of his own service was happily shifting from treatment to prevention, and the chapters on nutrition and the milk-in-school scheme in his report for 1936 made clear that he recognised the school medical service's changing responsibilities The following year, in his last report, he urged the need to re-examine its functions in the light of changing social conditions

After he retired in 1937 he continued his work at the university, and in 1941 he was appointed to the chair of social medicine He also wrote effectively and widely on public health hygiene, psychology, and mental deficiency More than most men he had resources in interests outside his own profession, and his study of history and archæology made his local histories of York and Birmingham valuable and scholarly works His chief interest was the antiquities of the Scandinavian countries He had translated Rathgen's *Preservation of Antiquities* and the official guide to the prehistoric collections of the Danish national museum, and he was a foreign member of the Society of Northern Antiquaries of Copenhagen as well as of the Society of Antiquaries of London

A colleague writes

Dr Auden built up an excellent medical service for the schools in Birmingham by inspiring enthusiasm for a new development He was rather impatient and suffered at times because others could not see so far ahead as he did, but the recent *Report of the Committee on Maladjusted Children* paid tribute to his far seeing view His interest and knowledge of those who are now called the handicapped was wide and tribute was recently paid him by the Birmingham Education Committee who named a school for the partially sighted after him This month's *Public Health* also refers to his recommendations

Dr Auden was extremely popular with his staff, always thoughtful and kindly, unassuming in his manner, with a strong sense of humour He was extremely versatile with many interests His erudition weighed lightly upon him, and yet it was glimpsed at times when he spoke of calling on a medical officer in Iceland and discussing Homer with him Passing years did not diminish his many interests He continued to attend the meetings of the Midland branch of the Society of Medical Officers of Health of which he had been a president He was a successful wood worker He wrote articles on many subjects His last, only a few years ago at the time of the Boat race, was on the longevity of oarsmen He kept up a lively and knowledgeable correspondence to the end *Multis ille bonis flebilis occidit*

Dr Auden leaves three sons one of whom is W H Auden, professor of poetry in the University of Oxford

---

Appointments

DUNCAN G D M B Aberd , D P H M O Leeds Regional Hospital Board headquarters

GORDON, N E M B Belf D P H M O H Todmorden, and divisional M O West Riding of Yorkshire

SIMS A J M B Lond F F A R.C S assistant anæsthetist Bury and Rossendale group of hospitals

Notes and News

THE INTERIM INCREASES IN REMUNERATION

SALARIES of hospital doctors and dentists up to and including the grade of senior registrar were raised by 10% from April 1 The corresponding increase for their seniors in the hospital service will be 5% from May 1 The new rates per annum for whole-time appointments (with the old rates in parentheses) are

CONSULTANTS

Appointed earlier than 31 —Starting salary £1890 (£1800)
Appointed at 31 —Starting salary £2047 10*s* (£1950)
Appointed at 32 or over —Starting salary £2205 × £131 5*s* to £3255 (£2100 × £125 to £3100)

The *maximum salary*, with the addition of the maximum distinction award, is now £5455, compared with £5300 previously

SENIOR HOSPITAL MEDICAL AND DENTAL OFFICERS

Appointed earlier than 31 —Starting salary £1548 15*s* (£1475)
Appointed at 31 —Starting salary £1601 5*s* (£1525)
Appointed at 32 or over —Starting salary £1653 15*s* × £52 10*s* to £2126 5*s* (£1575 × £50 to £2025)

As from May 1, 5% will be added to the aggregate net remuneration of general practitioners—i e , their remuneration after the deduction of practice expenses The Government propose that the method of distributing this extra money between individual doctors should be the subject of consultations with representatives of the profession The meeting of local medical committees last week recommended that the money should be accepted "without prejudice" and that negotiations should be entered into with the Ministry to decide the best method of distributing it

Dentists taking part in the general dental service will receive on average an increase of 5% on their net remuneration (before deduction of income tax) As practice expenses have to be taken into account, the actual increase will be 2 6% on the gross scale fees payable The increase will be payable on all payment schedules dated on or after May 1 For dentists working whole time at a health centre, the new scale will be

Grade I —£1575 × £52 10*s* to £2100 (£1500 × £50 to £2000)
Grade II —£1260 × £52 10*s* to £1575 (£1200 × £50 to £1500)
Grade III —£840 × £52 10*s* to £1207 10*s* (£800 × £50 to £1150)

Working in the National Health Service in Great Britain are over 10,000 senior hospital doctors and dentists, about 21,000 family doctors, and about 11,000 dentists The estimated cost of the two "interim adjustments" is nearly £6 million (senior hospital medical and dental staff, £1,200,000 , junior hospital medical and dental staff, £900,000 , general practitioners, £2,500,000 , dentists, £1,200,000)

EMPIRE RHEUMATISM COUNCIL

PRESENTING the report [1] of the Council for 1955–56, at the annual meeting held in the House of Lords on May 1, Dr W S C Copeman, the chairman, emphasised the importance of basic research in rheumatology lately reported It has, for instance, been shown by electron microscopy that there are many different varieties of muscle fibre , further research will be needed to decide whether this has a bearing on extra articular rheumatism

The report refers to work done by the Council's three fellows

Miss I H M Muir gives an account of the first isolation from cartilage of a complex of chondroitin sulphate and protein Small changes in its chemical structure lead to large physical changes, which may explain some of the changes in rheumatic conditions The linkage between carbohydrate and protein is probably an ester between the carboxyl group of a glycuronic acid and the hydroxyl group of serine An esterase, by disrupting such bonds, may lead to loss of elasticity and increase of permeability—an effect similar to that of hyaluronidase Miss Muir also reports the discovery of a new amino sugar (talosamine) in cartilage

Mr J K Norymberski, DR ING , reports biochemical studies of the steroid hormones—on the oxidation of corticosteroids with sodium bismuthate, the urinary excretion of cortico steroids in pregnancy, the ultraviolet absorption spectra of α ketols and the partial reduction of steroid hormones

Dr Madeline Keech has studied the structure of collagen and its possible relation to elastic fibres, and has been awarded the first prize in an international competition for the most outstanding contribution on the study of ageing

Other investigations referred to in the report include a controlled psychological comparison of patients with rheumatoid arthritis and their siblings , a study of antigen/antibody reactions , and a survey to find out the prevalence of rheumatic disease in Leigh, Lancashire, where a 4% sample of the population is having clinical and radiographic examinations and blood tests

The Council has launched an appeal for £250,000, in the hope that these promising lines of research can be followed up quickly and effectively

THE HEALTH OF EXECUTIVES

LAST year [1] Prof Alexander Kennedy gave an account of the hazards of being an executive (hazards both to himself and to his firm), and gave some guidance in the avoidance of breakdown in the "top management" of industry An essay on the Health of Executives by Dr V C Medvei [2] reminds us that many large organisations are coming to see the advantage of "treating their executives like expensive machinery"

Greater use of automatic control may tend to eliminate both the skilled craftsman and the worker at the moving belt , but the alphas (and probably the epsilons) of Aldous Huxley's brave new world will still be needed Even if the unpheavals and degradation are less than some people fear, the time when the top executive (Kennedy's "generaliser") is replaced by a robot is not to be foreseen On the contrary the current tendency to bigger and bigger organisations, which is creating Burnham's "managerial revolution," leads not only to an increase in the number of administrators but also perhaps to an increase in the sources of stress

Medvei regards "health" as signified by resilience, stamina, equanimity, and self reliance Many leading personalities possess these qualities , indeed the sickness rates are lower in persons with large responsibilities than in the multitude But even the higher resistance of these people may not suffice to protect them against breakdown if fatigue and stress are too severe Everybody has weak spots, such as a familial tendency to a certain illness, and the effect of the stresses to which executives are subject (such as anxiety, fear, worry and perhaps guilt , irregular timetables , and physical fatigue caused by travel, large meals, and alcohol) may act as triggers for illness Some cannot stand the pace and fall out , some can continue, but at the price of arterial disease or peptic ulcer , while a few seem constitutionally hardy, able to remain fit despite every strain Nothing can be done to give this hardiness to people who are not born with it , and the organisation which has them for its leaders is indeed lucky If the rest of the administrators are to avoid breakdowns, those who cannot stand the pace must be channelled into some backwater, and the middle group must be helped as much as possible

The wise organisation, Medvei says, will insist on its executives having enough leisure, holidays, secretarial help, and comfort in travel and at work (A New York textile firm has lately announced that its senior executives are to be given a week's holiday every seven weeks [3]) Thus hours and methods of work should be adapted to the individual one man will do as much in an hour (and be as exhausted at the end of it) as another in four hours , one works best at night, another in the morning Some firms have a scheme for regular medical examinations, even including X ray and laboratory tests But Medvei points to the danger of such overhauls on the one hand they make for a false sense of security, and on the other they make people conscious of their health and worried about it Moreover, an examination is not much use unless the physician is acquainted with the subject's background and the stresses he meets

The executive's life outside the office must be considered Here the social activities which are part of his work may be a burden These should be reduced to a minimum and perhaps shared by some of the juniors Board and committee meetings should be similarly pruned The executive should be warned against over exercise, and encouraged to relax (with an occasional sedative if need be) A change in surroundings and a hobby are both useful , a purposeful hobby that is not an obsession will give meaning to life after retirement

The head of an organisation, Medvei says, must be personally responsible for actively guarding the health of his colleagues , and a continuing partnership between physician and executive is needed to get the best results

THE BRITISH HOSPITAL IN PARIS

The Hertford British Hospital in Paris was first opened in 1871, to provide medical and surgical care for indigent British residents Lack of money forced it to close in 1952, but it has been redecorated and re-equipped to serve a dual function—the treatment of British soldiers and their families and (in conformity with Sir Richard Wallace s original endowment) the treatment of British civilians, for whom 25 of the beds are reserved French doctors and the doctors and nurses of the Royal Army Medical Corps will share the care of the civilians who will pay for their treatment if they can. The needy will be provided for by the administrators of the original Hertford Hospital, they will not be a charge to public funds

The hospital in its new guise contains 60 beds (in wards of not more than 3) including maternity wards as well as 2 operating-theatres and an outpatient department It was opened on May 3 by Lady Alexander

A PASTORAL CLINICAL COURSE

For some time it has been felt that future clergymen some of whom will become hospital chaplains should during their training acquire some knowledge of conditions in hospitals, especially mental hospitals Accordingly in the second half of March, a pastoral clinical training-course was held at Deva Hospital, Chester, and attended by first-year and second-year theological students from St Michael s College, Llandaff, Cardiff

The programme included lectures on mental disorders nursing, and related topics, with a talk on the Church s Ministry to the Sick, demonstrations of physical treatments and electro-encephalography, and visits to wards, classes, and recreational functions The students lived in the hospital and were favourably impressed by the atmosphere there, and thought the course of great benefit Several intend to return during the long vacation and work in the wards

The chaplain at Deva Hospital is the Rev. N W J Autton

NUTRITION RESEARCH AT COONOOR

The latest annual report[1] from Coonoor shows that the Nutrition Research Laboratories continue to flourish with a graduate staff of more than 30 These can be roughly divided into three groups—biochemists, clinical scientists, and public-health field workers Biochemical studies include the following

The vitamin B_{12} activity of the fæces of rats was found to be almost as high when the diet contained only vegetable proteins as when skim milk was given

In the rat there is a critical level of dietary protein necessary for the synthesis of liver enzymes (succinic acid dehydrogenase and xanthine oxidase) This is about 10% of protein in the diet At this level an adaptive mechanism can come into play which delays the effects of protein deficiency but 7 5% protein is clearly inadequate

The citrogenase activity of epiphyseal cartilage from rachitic puppies has been shown to be much below normal and the old problem of how vitamin D deficiency affects tissue metabolism is being studied

There is also a brief account of the chemical nature of the fatty acids in butter and beef fat which is a continuation of earlier work started long before this subject became fashionable

The clinical scientists have been concerned mostly with protein malnutrition

The hæmatological picture including bone marrow biopsy has been studied in 18 patients with kwashiorkor In most there was macrocytic anæmia sometimes with a megaloblastic reaction Improvement was usually slow even after treatment with folic acid or vitamin B_{12}

The cystine content of the hair of children with kwashiorkor was found to be low but the level of other amino acids tested was normal It is suggested that the cystine content of the hair may be a better index of the severity of protein malnutrition than the hair discoloration

In monkeys kept on a low protein diet for two to three months diffuse interstitial myocardial fibrosis was found

The public health work has been concerned chiefly with problems of infant feeding in South India

Detailed information about the quantities of breast milk secreted by the mothers supplements a previous study on the quality of maternal milk

A group of breast fed infants received daily 2 0 g of protein per kg of body weight in the first two weeks of life This figure fell gradually to 1 4 g after eight weeks and 1 2 g after twenty weeks The babies grew satisfactorily and the generally accepted figure of 3 5 g per kg for the protein requirements of infancy may be an over-estimate

The attractive feature of this report is the obvious close coöperation between the biochemists clinical scientists and public-health workers who are all centred on the laboratories This is a fortunate juxtaposition seldom found elsewhere It is now the fashion for young British graduates wishing to study abroad to look Westwards Any unconventional young man or woman who decided to go East might be well advised to spend time at Coonoor He would find the intellectual atmosphere in the Nilgiri Hills like the climate —bracing

Royal Commission on Remuneration

The commission held a meeting in Edinburgh on May 2 for preliminary discussions with the Joint Consultants Committee (Scotland) and the Institute of Chartered Accountants in Scotland This meeting was the eighth held by the commission

Medico-legal Aspects of District Nursing Practice

The Queen s Institute of District Nursing is holding a conference on Wednesday, June 5 at 2 30 P.M at Church House Westminster S W 1 when Dr J A Gorsky will open a discussion on this subject Applications for tickets should reach the institute, 57, Lower Belgrave Street, S W 1, by May 20

Conference on Medical Records

The Association of Medical Records Officers is to hold a conference from May 16 to 19 in Brighton Speakers will include Mr L E C Norbury F.R.C.S Mr A M Michie and Dr M P Curwen Further information may be had from Mr B B Bonner 11, Queensway, Horsham, Sussex

1742

West Midlands Physicians Association

The spring meeting of this association will be held at Holme Lacy Hospital, Hereford, on Saturday, June 1, at 11 A M

Institute of Dermatology, London

A semi permanent exhibition on the xanthomatoses, by Dr R H Meara, will be available at this institute, Lisle Street, W C 2, from May 5 to 29

London Hospital Research Building

This building, described last week (p 928), was opened on May 1 by Mr Dennis Vosper, the Minister of Health It was on view to a large number of guests, who were received by Sir John Mann, chairman of the board of governors

The Dentists and the Royal Commission

The representative board of the British Dental Association at a meeting on May 4 decided that " it would be in the best interests of both the public and the profession that they should give evidence to the Royal Commission on remuneration of doctors and dentists "

Chelsea Clinical Society

The annual dinner of this society will be held at the Rembrandt Hotel, Thurloe Place, London, S W 7, on Tuesday, May 14, at 7 30 P M The guests will include Viscount Hailsham, Q C , and Judge H C Leon

United Hospitals Choir

This choir is to give a choral and orchestral concert in October, including works by Purcell, Schubert, and Handel Rehearsals are held on Thursdays (7 30 P M to 10 P M) at the Pulteney School, Peter Street, Soho, London, W 1 Further details may be had from the secretary, Miss J Magrath, 18, West Side, Clapham Common, S W 4

London Amateur Boxing Association

A meeting of the medical officers of this association (69, Victoria Street, S W 1) is to be held at the Great Northern Hotel, King's Cross, on Wednesday, May 29, at 8 P M , when Dr J H Taylor will speak on psychiatric aspects of head injuries

South East Metropolitan Regional Hospital Board

Dr J S S Fairley has been appointed senior administrative medical officer of the board in succession to Dr H L Glyn Hughes, who is retiring

Dr Fairley studied medicine at the University of Cambridge and qualified in 1928 taking his M B two years later After holding house appointments at the General Hospital, Birmingham, he settled in general practice in that city In 1938 he proceeded to the degree of M D As a territorial officer he was called up in 1939 and later in the war he served as D A D G , Army Medical Services, at the War Office In 1945 he was appointed assistant director of personnel to the Emergency Medical Service Since 1947 he has been deputy senior administrative medical officer in the South East Metropolitan region.

Mental Hospitals

At their eighth annual general meeting on April 27, the Friends of Menston Hospital (near Leeds) passed a resolution calling the attention of the Minister of Health to the following " appalling admission " in the Ministry's report for 1955 (p 123)

> For it may well be that the hospital system reinforced by some inevitable stagnation during the war years is responsible more than disease for the fact that many patients have become chronic and deteriorated

The resolution says that " many relatives and friends who are in the grievous position of helplessly observing their patients suffering from a gradual process of deterioration, have long suspected, with deep concern and indignation, that prevailing conditions in many mental hospitals are a major contributory factor in this process Whilst welcoming official recognition of a situation that can only be regarded as intolerable, this Association now demands an assurance from the Minister of Health that urgent steps will be taken to accelerate and extend, on a scale more commensurate with the gravity of the problem, such efforts as are at present being made for the improvement of our mental hospitals "

Sir Russell Brock Dr Paul Wood and Mr Rodney Maingot are attending the Middle East Medical Assembly in Beirut Lebanon, from May 10 to 12 under arrangements made through the British Council

Mr A S Parkes SC D F R S is visiting Yugoslavia from May 5 to 25 at the invitation of the Yugoslav national commission for UNESCO and the British Council to lecture on the work of the division of experimental biology of the National Institute for Medical Research

Diary of the Week

MAY 12 TO 18

Sunday, 12th

King's College Hospital Medical School, Denmark Hill, S E 5

SURGEON TO MOORFIELDS, WESTMINSTER, AND CENTRAL EYE HOSPITAL, LONDON, OPHTHALMIC SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

THE dangers of over-specialisation in medicine and surgery have in recent years been stressed on both sides of the Atlantic Ocean, and we often hear people say that the great clinicians of the 19th century had far more bedside acumen than is evident in their successors today I suppose we would all agree that a firm background of general medicine is desirable for specialists On the other hand we have to sympathise with those who settle the medical curriculum, because nearly all specialists, including those who are most vocal concerning the dangers of over-specialisation, maintain that their *own* specialty should be allotted more space in the curriculum

Were those old physicians really so wise ? They had their fads, and many of the pronouncements which fell with such dogmatic emphasis from their lips would immediately have been disproved by a modern pathologist or biochemist Moreover their training, we are told, was much easier Surgery had a limited range, and the technique of special investigation was so simple For these and other reasons an attempt has been made to show that our distinguished forebears had feet of clay, and that they would not have achieved much in the present medical set-up

Shall we join in this debunking ? I would say "no" Some few of these former giants may perhaps have become prominent because of circumstances peculiar to their time, but the greater number, I feel sure, would have done great work at any epoch Addison and Osler could never have been insignificant in their profession Nor could Jonathan Hutchinson (1887), who said about dermatology seventy years ago that "beyond all others it offers attraction to the student of the laws of disease, and to the seeker after the causes which disturb health and local nutrition" He was quite right Some branches of modern medicine have little obvious relationship with each other, and only slender links with general health; but nobody can reasonably deny that the skin and the eyes can act as mirrors to each other and to the whole bodily state. Let us now inquire into the overlap

The Overlap between Dermatology and Ophthalmology

Bearing in mind that certain differentiated elements in the eye are derived from the embryonic ectoderm, we should naturally expect that some of the hereditary and environmental factors which help to determine the state of the skin should also influence the eye That expectation is abundantly fulfilled, because in fact we find innumerable instances of parallelism in dermal and ocular pathology Thus thyroid deficiency can bring cataract as well as alteration in the skin texture Another disease notorious for attacking eyes and skin is Boeck's sarcoidosis Fundus lesions may be associated with sebaceous adenoma of the face in epiloia Facial nævus can supply the clue to retinal angiomatosis in Hippel-Lindau syndrome Von Recklinghausen's disease also manifests itself in the eyes as well as in the skin.

Then again, the eyelids, which normally serve as eye-shields, can act as a bridge by which infection and other noxious agents travel from the skin to the eyes Therefore topical therapy of the facial skin must sometimes be modified *in order to avoid ocular damage*—and vice versa That is to say, various medicaments applied to the eyes have been known to set up a dermatitis not necessarily confined to the face Furthermore the lids themselves are a favourite site for basal celled carcinoma, and may be implicated in and distorted by facial lupus Xanthelasma, xeroderma pigmentosum, and psoriasis are among the many diseases that have occurred in the palpebral skin, and they can all produce consecutive changes in the eye A host of different organisms, including moulds and protozoa, has also been identified, so that the pathology of the eyelids, considered in relation to their size, is extraordinarily varied

Nearly all the acute infectious fevers that have been known for centuries are characterised by a rash, and many of them also provoke ocular complications In most countries syphilis has become so much less common than it was a generation or two ago that we often forget its existence nowadays, but in fact the spirochæte can still produce a wide range of skin and eye lesions, and occupies an important place in differential diagnosis Among the skin diseases which can create ocular havoc few can be more distressing than certain vesico-bullous outbreaks of obscure origin Pemphigus, which is their prototype, not *uncommonly destroys the sight of both* eyes

As the skin of the eyelids is more sensitive than any other part of the integument, it is commonly the first to become affected by noxious physical and chemical influences, and may also flare up in consequence of dermatitis beginning elsewhere Palpebral skin is also vulnerable to numerous nutritional defects, including shortage of vitamins Styes were often attributed in former times to refractive errors, ocular muscle imbalance, and other sources of eye-strain, but that explanation now seems doubtful. More probably styes are simply the expression of a temporarily lowered resistance to staphylococci, being analogous to boils in other parts of the skin

It would be easy to multiply instances of diseases in which the dermatologist and ophthalmologist are jointly concerned, but the reasons already given are enough to underline the need for coöperation between the specialties Before we go on to consider some of the relevant changes in exposed skin, I should like to say that I have always found skin physicians most helpful, and I am convinced that they can offer the ophthalmologist more than he is able to return

Significance of the Exposed Skin

Mistakes in diagnosis, and delay in arriving at a correct diagnosis, could often be prevented if we were to examine the whole body-surface For instance, I remember a case of orbital carcinomatosis being at first misinterpreted because the patient protested that she was and always had been perfectly well, apart from recent stiffness and hampered movement of her left eye She was afterwards found to be harbouring a scirrhus carcinoma of the breast This growth had started sixteen years before but she had steadfastly refrained from mentioning it to anybody. Returning to skin problems, we have all encountered or recently heard about women presenting themselves with blepharitis and not saying anything about the primary seat of trouble—e g , dermatitis of the thigh caused by a nickel containing suspender buckle

We could all recite a series of examples to show the practical value of a complete examination, but unfortunately time is fleeting, and few ophthalmologists could ever get through their work if they had to make every patient strip So much the more, then, should we strive to make use of the information vouchsafed by whatever skin is open to view. Clearly the face is the most important, but we should never neglect the head and neck, and even the hands can supply valuable pointers Not long ago a patient with failing vision presented me with an immediate clue in the form of fingers stained brownish-yellow. Detailed examination afterwards confirmed the "spot" diagnosis of tobacco amblyopia.

---

* A lecture given on April 5, 1957, at the 30th annual spring congress of the Gill Memorial Eye, Ear, and Throat Hospital, Roanoke Virginia, U.S.A

Syphilitic stigmata of the face are less common than they were, but they furnish a good example of how skin changes can throw light upon associated eye trouble. Another obvious link is provided when iridocyclitis arises at the peak of a herpes zoster ophthalmicus rash, or scleritis as a sequel, by which time the characteristic pitted scars will be visible. Rosacea as a cause of conjunctivitis and keratitis is now so well known that we might be tempted to blame anyone for missing the facial signs. It is only fair to point out, however, that these signs can swiftly alter, and that the eyes may be severely involved without there being any conspicuous rash on the face.

Blepharitis is often an infection limited to the eyelids, and it can also be a form of allergic reaction; but sometimes it is merely part of a facial seborrhœa, and thus in its turn is typically associated with masses of dandruff. In such cases a spirit lotion to the scalp, together with facial treatment and regulation of diet, will often clear up the blepharitis even if little or no treatment be directly applied to the lids. Dryness and desquamation of the face arising for the first time in a middle-aged or elderly patient should make us think of diabetes. Pallor and fine parchment-like wrinkling of the facial skin has more than once been noted in patients suffering from pituitary growths. Pigmentation can appear for a multitude of reasons, including pregnancy, Addison's disease, systemically administered arsenic, and industrial exposure to silver nitrate. Two of the most interesting cases I ever examined were twin brothers in their early 30s. They both had swarthy faces and early bilateral cataract, and they died of hæmochromatosis within a few months of each other.

Enthusiastic physicians often combine amusement with the exercise of their skill by trying to diagnose the ailments of casual acquaintances or fellow-passengers. That is a fruitful pastime which many of us have tried, and it is astonishing how many vital facts can unobtrusively be gleaned. When we come to assess our own patients we start with the initial advantage of having heard their complaints and plied them with questions. Careful history-taking, together with alert preliminary inspection from a distance, will strongly indicate the diagnosis in a large proportion of cases, and the corollary is true: that is to say, we shall certainly commit unnecessary blunders if we plunge into direct ophthalmoscopy without first making a general survey.

Disturbance of the Palpebral Skin

The eyelids are a miniature museum of pathology. They can be the seat of various neoplasms, primary or secondary, and they often register events in remote parts of the body. For instance, a small hæmorrhage in one eyelid may be the first obvious sign of a medullary neuroblastoma; and suffusion of all four lids with blood is a classical sign of vitamin-C defect. Œdema can arise not only from infected meibomian cysts and other inflammatory lesions of the eyelids or eyes, but also in consequence of dental abscess, food-poisoning, or renal failure. Blepharochalasis is the name which Fuchs (1896) applied over sixty years ago to a so-called idiopathic form of palpebral œdema, intermittent at first, later becoming constant, and not attributable to any known local or systemic malady.

Dermatitis of the eyelids is perhaps the most important of all the subjects that jointly concern skin and eye specialists. There are many different ways in which lid eczema can be classified; but let us first consider, without any attempt at differentiation, what signs are relevant.

1. *Change of colour* is important because it can be recognised from afar in all but the slighter degrees. Acute dermatitis of recent onset often produces a pink flush, but brownish discoloration suggests longstanding trouble. In chronic marginal blepharitis the lids may turn dark red.

2. The *eyelashes* may be altered in colour or diminished in number. Crusts of dried secretion are sometimes found entangled, and the line of eyelash growth may be distorted.

3. The *skin surface* may show fine additional wrinkles, branny desquamation, fluid droplets, adherent crusts, or even *lichenification*. There may be fissures, especially at the outer canthus or underneath a redundant fold (cf., intertrigo beneath pendulous breasts).

Even if the causation of a patient's lid eczema is obscure at the original examination, we are more likely to track it down if we set out a written description of all these items straight away; and coloured photographs taken at intervals are particularly valuable in cases of lid eczema.

Psychosomatic Considerations

We sometimes hear people talk as though psychosomatic medicine were an entirely modern concept, but of course the notion of bodily states being produced or aggravated by stress of mind is as old as history. Jonathan Hutchinson (1876) was aware that severe cheiropompholyx is as a rule associated with a highly nervous temperament, and he said that this disease "must certainly be regarded as a neurosis." Psychosomatic medicine is no new thing, but it certainly looms much larger in medical thought than ever before, and some of its extremists have laid themselves open to ridicule.

The fact that the skin can in so many ways mirror the mental state does not mean that we should ignore other factors—e.g., heredity, infection, and allergic susceptibility—which help to produce dermatitis. We must also remember that skin lesions are in themselves a source of worry. Sensitive people with a pride in their appearance and the habit of personal cleanliness are naturally distressed by rashes or blisters on exposed areas of their skin. The friends who tactfully avert their gaze can embarrass such a patient almost as much as do those others who rake the blemish with an inquisitive stare—and the neurosis that ensues may be misinterpreted as the cause, not the effect, of the dermatitis.

Clearly some skin diseases, such as rosacea, are far more closely linked with an anxious state of mind than was formerly recognised, and at the other extreme are conditions mainly or exclusively due to material factors; but much of the ground is debatable. It is not always possible to say whether a given instance of skin trouble arises from mental disturbance. We know that, of two morphologically identical congenital defects, one may be truly hereditary and the other due to intra-uterine inflammation. Similarly neurodermatitis can imitate or be imitated by eczema of quite different origin. Great judgment is needed to apportion the relative responsibility of body and mind in skin upsets, and no man is wise enough to be right every time. How could he be, when the mind and body are so inextricably interwoven that "never the twain shall *separate*"?

Subject-matter of Dermo-ophthalmology

No comprehensive classification of dermo-ophthalmology will here be attempted, but let us now consider a few of the important groups encountered in practice.

1. *Dermatitis of the Eyelids*

We have already seen that lid eczema may be part of a widespread seborrhœic state. It is also a common manifestation of rosacea. Another potent source of trouble is neglected conjunctivitis, especially among children, who so often introduce staphylococci by plucking at the crusts entangled in their eyelashes. Unless we act quickly to remove the dried secretion and discourage the patients from touching their lids, severe

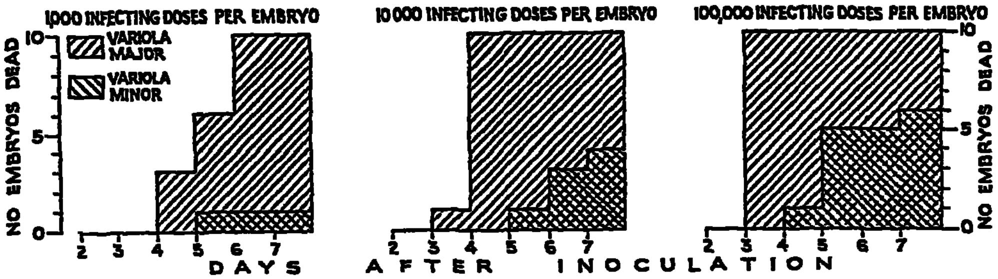

Fig 2—Cumulative deaths of chick embryos after inoculation of three different doses of variola major and variola-minor viruses on the chorio-allantois

(1) To determine the rate of growth of virus on the chorio-allantois the inoculum was about 150 pock-producing doses After one, two, and three days the eggs were opened and the chorio-allantois removed for estimation of the virus

(2) In the experiments designed to follow the rate of virus increase in the livers of chick embryos 10^4 infective doses of virus were used as inoculum on the chorio-allantois Each day thereafter two embryos of each series were examined, and their livers were removed with sterile precautions, weighed, and pooled Suspensions of chorio-allantois and of liver were made by shaking them mechanically in 'Universal' containers with glass beads and a known volume of 12% broth in distilled water with penicillin Debris was removed by low speed centrifugation, and the supernatant fluids were used for titration Pieces of liver were fixed with 10% formalin and stained with hæmatoxylin and eosin

(3) For a comparison of mortality-rates of chick embryos after inoculation of the chorio-allantoic membranes, three different doses of inoculum (approximately 10^3, 10^4, and 10^5 infective doses) were used Ten embryos were inoculated with each dose Eggs were candled daily and the number of dead embryos recorded up to seven days, when the observations were terminated

Titration of Virus

The virus content of suspensions was estimated from the number of specific lesions formed on the chorio-allantois three days after the inoculation of 0 1 ml volumes of serial dilutions The estimation of titre was made from membranes inoculated with that dilution which gave a mean count of 20–200 lesions For titration of the purified suspensions used as inoculum in various experiments tenfold dilutions were tested near the expected end-point, four eggs being used for each dilution For experiments in which the virus content of chorio-allantoic membranes or of livers was compared, the supernatant fluids from extracts were tested in tenfold dilutions, two eggs only being used for each dilution Though this method could not provide accurate estimates of the concentration of virus, the results proved adequate for comparing variola major and variola-minor strains of virus

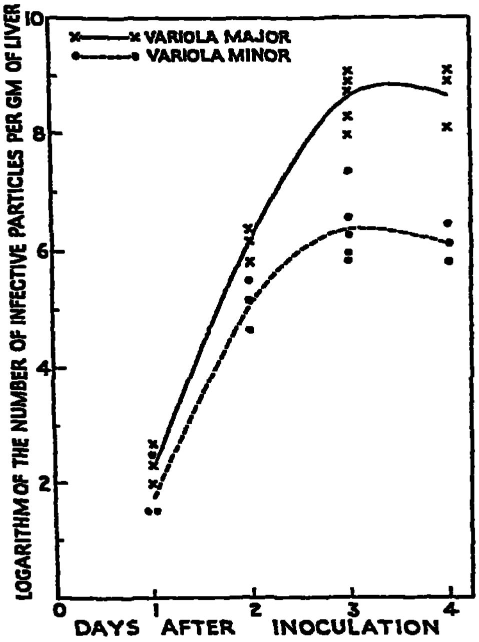

Fig 1—Amounts of virus recovered from chick-embryo livers infected with either variola major or variola minor strains

Results

Recovery of Virus from the Chorio allantois

Increasing amounts of virus were recovered from eighteen to seventy-two hours after inoculation, and the rate of increase was logarithmic for the first forty-eight hours On the second and third days after inoculation membranes infected with variola-major strains gave more virus than did those infected with variola-minor strains This difference was never greater than twofold but was constantly found with all pairs of virus strains tested

Recovery of Virus from Chick-embryo Livers

Virus was recovered from chick-embryo livers twenty-four hours after chorio allantoic inoculation, and there was a steady increase in the amount recovered during the following forty-eight hours Fig 1 shows the results obtained with the five pairs of virus strains tested From forty-eight hours after inoculation more virus was always recovered from embryos infected with the variola-major strains The livers of these embryos showed at least fifty, and usually several hundred, times as much virus as did those infected with the variola-minor strains

Histological changes in infected chick embryo livers—Fatty degeneration affected the livers of embryos inoculated with either virus but became more conspicuous in those infected with the variola-major strains On the second day after inoculation with variola-minor virus the livers showed mononuclear-cell infiltration, which later became very extensive Livers of embryos infected with comparable doses of variola-major virus, on the other hand, showed only slight mononuclear infiltration, which did not appear until the fourth day after inoculation, when many of the embryos were dead The more rapid rate of increase of variola-major virus, associated with a greater degree of hepatic degeneration, appeared to have impaired the defence mechanisms of the embryo

Mortality of Chick Embryos Inoculated with the Viruses of Variola Major and Variola Minor

Chick embryos were observed for a week following the inoculation of comparable doses of virus strains Four of the three hundred embryos inoculated died on the first day of the experiments and none on the second day Deaths taking place later than the second day were considered specific From the third day after inoculation the total mortality rate varied directly with the dose of virus, and the survival time increased as the dose became smaller

The mortality was greater and deaths took place earlier after the inoculation of variola major virus This difference was found with all the five pairs of virus strains tested Fig 2 shows the cumulative total numbers of embryos dead each day after inoculation with comparable doses of the first pair of virus strains listed in the table These experiments were not designed to measure statistically the dose of virus producing a 50% mortality-rate (L D 50), but with each pair of strains the approximate L D 50 of the variola-minor virus was at least ten times greater than that of the corresponding variola major strain

Discussion

The observations recorded here indicate that the five strains of variola major virus were more virulent for the chick embryo than were the five strains of variola-minor virus tested in parallel This difference in virulence is not apparent in the character of the lesions produced on the inoculated chorio allantois, on this tissue the naked-eye and histological appearances of the pocks produced by the two viruses are identical It is manifested after chorio-allantoic inoculation by the greater multiplication of the virus of variola major in the livers of the embryos and by the greater mortality when tests are made with approximately similar inocula of the two viruses The chick embryo has been used to elicit similar differences in virulence of other pox viruses—e g, between strains of ectromelia virus (Fenner 1948) and between cowpox virus and its white variant (Haddock 1952) The difference shown by Dinger (1956) between the survival of variola major and variola-minor strains on the chorio allantois may, in part, be consequent on greater multiplication of the major strains in the tissues of the chick embryo

Constant differences between the two kinds of smallpox virus were not found in our experiments with mice and rabbits, nor by F O MacCallum, in tests with suckling mice, suckling rats, or suckling hamsters As serological methods have not differentiated the viruses, the chick embryo seems to offer the best means of identifying the type of smallpox virus in the laboratory This may be important in isolated cases of smallpox or in outbreaks involving only one or two patients, when there may be no clear clinical indication of the identity of the infecting strain The laboratory investigation of such strains, however, would require about a fortnight to complete The tests would involve the comparison of the virulence of the fresh strain for chick embryos with those of known variola-major and variola minor viruses, using comparable infecting doses determined by preliminary titration of the viruses by the pock-counting technique on the chorio allantois

Summary

Five strains of variola-major virus were compared with five strains of variola-minor virus as regards their virulence for the chick embryo when inoculated on the chorio-allantois

With comparable infective doses the variola major strains constantly produced a much greater mortality in the chick embryos The greater virulence of these strains was associated with the presence of much more virus in the livers of the embryos from two to four days after inoculation

These findings indicate a method whereby the virus laboratory could assist in the differential diagnosis of variola major and variola minor

ABSENCE OF RAYNAUD'S PHENOMENON IN WORKERS USING VIBRATORY TOOLS IN A WARM CLIMATE

The Raynaud phenomenon is induced by exposure to cold (Hunt 1936a) and precipitated by the use of vibratory tools (Hunt 1936b) In cold weather people working with vibratory tools often display this phenomenon on their way to work, especially if they use a bicycle or a motor cycle, but symptoms may disappear during work when the body warms up (Marshall et al 1954)

Raynaud's phenomenon is unknown among men using vibratory tools in Singapore, and it was therefore of interest to find out whether it is either masked or prevented by a warm climate Singapore is within 1½° of the equator, and its climate is uniformly warm, the maximal limits of diurnal and seasonal variations being about 20–34°C (68–93°F), but the temperature very seldom falls below 22°C (72°F) or rises above 33°C (91°F)

Methods

31 dockyard workers, aged 24–53, using vibratory tools at H M Dockyard in Singapore were investigated at random 16 of them were Chinese, 10 Indians, and 5 Malays 28 had worked with vibratory tools for at least three years, and 10 of these for fifteen years or longer All riveters and caulkers had used vibratory tools for 80–120 hours a month during the past two years but the scalers used vibratory tools only for 120 hours each alternate month

3 controls were used A, a male Chinese clerk, aged 35, recovering from hæmatemesis, B, a male Chinese physician, aged 30, who had lived in Singapore since birth, and C, a European physician, aged about 45, in transit through Singapore In England on his way to work, in the winter he constantly suffered from Raynaud's phenomenon He had so suffered a few days before being tested on the spur of the moment, without preliminary general cooling All the controls had very little subcutaneous fat

All the tests were conducted in a temperature controlled room at 10 5°C (51°F) ±2°C The men wore tropical clothes but no shoes or socks, and they were tested in groups of 3 while lying still on stretchers of woven cane

The skin-temperature of the palmar surface of the distal phalanx of the little finger of both hands was recorded with a bare thermocouple (Glaser 1949), a 'Cambridge' vernier potentiometer, and a 'Cambridge' spot galvanometer A period of not less than 75 minutes was allowed to enable the men to complete immediate thermal and postural adjustments Previous evidence has shown that this length of time is adequate for the skin temperature to stabilise (Glaser and Newling 1955)

The blood pressure was recorded with a sphygmomanometer by auscultation of the brachial artery several times during this preliminary period After the preliminary period each man immersed his right hand and wrist in water at 10°C (50°F) for ten minutes. Anteroposterior radiographs of both hands and wrists were taken from the dockyard workers on a subsequent occasion. The European control was tested after only fifteen minutes in the cold room.

---

* Present address Department of Physiology, London Hospital Medical College, London, E 1

Tools and Work

The vibratory tools were driven by compressed air. They were either riveting tools giving 1600 blows a minute or scaling, chipping, and caulking tools giving 1700–3050 (average 2100) blows a minute.

These tools and their methods of operating were the same as in British dockyards, except that the riveting machines were often supported by a sling. A common fault was that the riveting hammer was not always held close against the head of the rivet, causing frequent rebounds and breaks. The average number of rivets driven in was 100 daily, although up to 300 a day is not uncommon in England. Riveting hammers were held in the left hand and opposed by the right hand, but scaling and caulking machines were held in either hand.

Results†

One workman, aged 53, showed a rise of blood-pressure to 250/140 mm. Hg during the initial period of cooling and was not allowed to continue the experiments, leaving 30 dockyard workers to immerse their hands in cold water. Inspection of the hands before the tests showed no evidence of any of the small skin lesions associated with Raynaud's phenomenon.

During the preliminary period of cooling the finger-temperature of the dockyard workers invariably remained 2–8°C above the room-temperature, and there was only one instance in which the skin-temperature of one finger fell just below 14°C, which fact suggests that the resting circulation in the fingers of these workers was adequate. The skin temperature of the left hand was always lower than that of the right hand, and no satisfactory explanation can be advanced for this. There was no evidence either of cyanosis or of pallor of the fingers among the workers at any stage of the experiment, and none of the workmen complained of pain in the hands or of numbness in the fingers when their hands were not immersed in cold water. During immersion none of them considered the pain severe.

On radiological examination 6 of the 31 workers were found to have minimal cystic changes in the bones of the hand, and there was some suspicion of cystic changes in 1 other man. These findings were equally frequent in both hands and were not confined to those men who had used vibratory tools for the longest time, because 3 men who had used these tools for only 2–4 years showed such changes. 4 dockyard workers, including 2 without cystic changes, were reported to have mild osteo-arthritis of the wrists. In a control group of 36 Asian men (11 of whom were aged 25–39, 13 aged 40–49, and 12 aged 50–58) only 2 (aged 35 and 57) had minimal cystic changes, and 4 had early osteo-arthritis.

In control B, who was tested in exactly the same way as the dockyard workers, the finger temperature fell to within 1°C (2°F) of the room-temperature after an hour in the cold room. When his hand was immersed in water at 10°C (50°F) he developed cyanosis of the fingers and a severe and painful swelling in the dorsum and in all fingers of the immersed hand, followed by persistent swelling and pain after he had returned to a warm environment.

Control A had pain, and his fingers were pale, with purplish patches, after an hour in the cold room and before immersion of his hands in cold water. During immersion the pain became worse, but the fingers did not swell. Control C, who was tested without a preliminary period of cooling, did not develop any symptoms or signs of Raynaud's phenomenon.

Discussion

Hunter et al. (1945) had observed in England that 81% of riveters and 61% of caulkers in a large group had signs of Raynaud's phenomenon; even among those who had used vibratory tools for only two to five years about a third showed symptoms of this phenomenon. The absence of Raynaud's phenomenon among the dockyard workers taking part in the present investigation was therefore probably due to the fact that they were living in a warm climate. The method used in the present investigation was adequate, however, to produce symptoms of the Raynaud phenomenon in two controls (A and B). In control B symptoms and signs were severe; he had been frequently exposed to vibration and cooling because he rode a motor-cycle, and he spent much of his time in an air-conditioned theatre, where his hands were exposed to localised cooling by volatile anæsthetics and alcohol. This suggests that vibration produces symptoms of Raynaud's phenomenon only under conditions of intermittent cooling.

It is unlikely that the absence of Raynaud's phenomenon among dockyard workers in the present investigation was due to any other cause. Changes accompanying acclimatisation to heat could not have had a decisive protective effect, because such acclimatisation to heat was present in two controls (A and B), who displayed the phenomenon, and absent in the other control (C), known to show the Raynaud phenomenon.

The finding that control C, who had been inadequately cooled, did not develop Raynaud's phenomenon though he had suffered from it a few days earlier in England, conforms to findings of Hunt (1936a), who could not produce this phenomenon unless the whole body was cooled. This is further supported by evidence that the blood-flow to the skin depends not only on thermal impulses arising from the skin but also on the temperature of the deep tissues and on previous cooling or warming of the body (Glaser and Newling 1955, 1957). The fact that men in Singapore drive in fewer rivets a day than do workers in England could not explain the complete absence of the Raynaud phenomenon among Singapore workers; nor could the suspension of the riveting hammer by a sling provide complete protection, because such slings are sometimes used elsewhere.

The finding that cystic changes were present in nearly 20% of the workmen investigated, whereas Raynaud's phenomenon was completely absent, bears out a suggestion by Hunter et al. (1945) that cystic changes are not caused by vibratory tools but by repeated jarring. Such jarring was common among the dockyard workers in Singapore.

Conclusion

A reasonable conclusion is that an investigation on the lines of the present experiment, involving thorough cooling of the whole body as well as immersion of the hand, would show up potential sufferers from the Raynaud phenomenon.

If all those intending to use vibratory tools were tested in this way, it would be possible to classify Raynaud's phenomenon as an industrial disease and to eliminate the objection against such classification (Beney 1955).

Alternatively, thorough general warming of the body and hands before starting work in work places heated to relatively high environmental temperatures might be advantageous.

Summary

30 men using vibratory tools in an equatorial climate were tested in a cool environment by immersion of a hand in cold water, but none showed any signs of Raynaud's phenomenon.

---

† Copies of a table setting out the results more fully may be had from THE LANCET office, 7, Adam Street, Adelphi, London W.C.2.

The evidence suggests that vibration induces the Raynaud phenomenon only if there is also intermittent cooling of the body and of the hands

The Raynaud phenomenon could be classified as an industrial disease if all those intending to use vibratory tools were suitably tested beforehand

We thank the Commodore Superintendent of H M Dockyard, Singapore, for permitting the experiments to be made, the Chief Contractor and his staff for their generous cooperation, and Dr A M Poutsma, of the General Hospital, Singapore, for reporting on the X-ray films and for advice

A SERIOUS HEAD INJURY IN A PREGNANT WOMAN

TREATED BY HYPOTHERMIA

G F Rowbotham
B Sc Manc, F R C S
SURGEON IN CHARGE

Kathleen Bell
M B Durh
SENIOR CONSULTANT ANÆSTHETIST

Jean Akenhead
S R N
NURSING SISTER

Audrey Cairns
ACTING RESEARCH SECRETARY

From the Regional Centre of Neurological Surgery at the General Hospital, Newcastle upon Tyne

On May 4, 1956, at 2 45 P M, Mrs Ellen Moore, aged 22, was walking along the pavement pushing her only child, aged 18 months, in a perambulator In the morning she had been to the antenatal clinic and had been told that she was about eight weeks' pregnant In the afternoon she was escorting her mother to the bus stop when a heavy tree trunk, 30 feet long, rolled off a lorry and knocked her head first into a wall Witnesses said that they found her lying on the ground as if dead She was admitted to the neurosurgical unit at 3 15 P M

Acute Phase

Examination

On examination she was in deep coma, without even the swallowing reflex She lay supine, with legs extended and stiff Her arms were stiff, straight, and pronated, her wrists and metacarpophalangeal joints were flexed and her fingers extended Both plantar reflexes were extensor Both pupils were widely dilated and did not react to bright light Her face had lost its expression her mouth was open, and her tongue had fallen backwards Breathing was light and rapid, 38 per min, the pulse rate was 100, the blood pressure 120/80 mm Hg, and the skin temperature 101°F

There was profuse bleeding from her left nostril and ear, and she had a large hæmatoma and a laceration on the left side of the head Her left eyelids were swollen and discoloured, and there were signs of a massive intraorbital hæmorrhage The bones of her limbs and neck were intact, no obvious thoracic or abdominal injury was detected

Radiography a fortnight later (May 17) showed a fissure fracture extending downwards from the parietal region through the squamous temporal bone into the floor of the middle fossa, probably on the left side

Diagnosis

The speed and depth of unconsciousness made it certain that her brain had been severely damaged Also, the nature of the injury made it likely that, apart from extensive neuronal paralysis, which might or might not be reversible, there were scattered contusions and possibly lacerations of the cerebral hemispheres, particularly the temporal lobes The decerebrate rigidity pointed strongly to damage in the upper part of the brain stem, though the exact nature of the damage must be conjectural

At this point it was impossible to know whether or not a surface blood clot was present, or forming, that could profitably be removed surgically There were no lateralising neurological signs Before a decision on whether to open the head was forced on us, and before we felt it necessary to do a lumbar puncture, the patient's temperature began to rise ominously, and we felt it imperative to resort to antipyretic therapy and to take a chance on possible compression of the brain This is the type of case that so commonly ends fatally within three days

At 2 A M on May 5 her condition was much the same except that the muscles of her limbs were a little less spastic, but, though excessive warmth had been deliberately avoided, her temperature began to rise By 10 A M the skin-temperature was 105 5°F and, judged by the slope of the rise, was still on the way up Past experience has proved that simple cold sponging and intravenous aspirin often fail to control malignant hyperpyrexia in cases such as this, and therefore we decided to try the new method of cooling

Hypothermia (K B)

The object of hypothermia in head injuries is twofold (1) to counteract hyperpyrexia resulting from disturbed function of the heat centre, and (2) to slow up excessive and harmful reaction to the injury, and to diminish metabolic requirements while the damage to the brain and other tissues is undergoing repair

May 5—An intravenous drip was set up at 11 A M, and a *solution of chlorpromazine* 25 mg, *promethazine* 25 mg, and pethidine 25 mg in 540 ml of physiological saline solution was given at the rate of 3 pints per day—i e, a daily dose of 75 mg of each drug Then the patient was completely stripped, and the overlying bed clothes were removed The patient was sponged with ice water, and her limbs, body, and head were packed about with ice bags, cold air was also blown across the bed

By 6 P M—i e, seven hours after the start of the drip—the rectal *temperature* had dropped by stages to 30°C By this time the depth of consciousness was still the same, but the hypertonic limbs had become flaccid, the respirations were 40 per min, the pulse rate 120–150, and the blood pressure 118/70

To prevent infection a course of intramuscular sulphadiazine was begun A stomach tube was passed with difficulty and *feeding started*

May 7—Though there was now evidence of return of the swallowing reflex, tube feeding was still necessary The pupils were less dilated and reacted faintly to light The muscles were regaining their tone from the secondary *state* of flaccidity into which they had passed on the institut*ion of* cooling Respirations 35 per min, pulse rate 120–150, blood pressure 90/50

May 8—There was some lightening of coma, and the patient *groaned and moved* when disturbed for nursing purposes She was, however, still deeply unconscious, and all the muscles of her limbs were spastic Respirations 18 *per* min, pulse rate 140–150, blood pressure 120/80

May 9—Coma was a little lighter, limbs were *spastic* At this stage the intravenous drip was taken down and the drugs were given per rectum chlorpromazine *100* mg, *promethazine* 100 mg, and pethidine *200 mg daily*

May 11—The patient was still deeply unconscious, and all her limbs were spastic Cooling was discontinued at 8 P M

During this period of seven days' cooling the rectal temperature was as low as 30°C and as high as 36°C Our design was to keep it between 30°C and 34°C, and during the period of cooling the mean lay somewhere between these figures *After the lowering of the* temperature to 30°C the ice bags were removed, and cooling was maintained mainly by keeping the patient unclothed and uncovered by bed clothes, with occasional damping with cold water, aided by potentiating drugs

The patient was fed with special protein and *vitamin* foods because even at a temperature of 30°C metabolism, though substantially damped, is still active The blood-pressure ranged between 96/58 and 120/80 mm Hg, and the pulse rate remained fast, but the respiration rate fell from 52 to 16 At no time was there any anxiety about the firm and regular action of the heart, though its rate of beat fluctuated considerably between 150 and 100 per minute Before cooling was started the muscles of the limbs were already becoming less spastic, but they became definitely flaccid in the cooling stages, later to become spastic What the effect of low temperatures may be on spasticity is still uncertain, but judged by other cases spasticity seems to lessen in lower temperature ranges, though associated drugs may contribute to this

At the end of the period of cooling the patient was dried with a towel, covered with one blanket, and allowed to warm up slowly as other coverings were slowly added to the bed Three days after cooling her temperature went up 1° above normal but it was soon lowered by simple sponging, and we never again had any anxiety about hyperpyrexia

Stage of Cerebral Irritation

On June 4 the patient became one of the most difficult problems that a medical service ever has to cope with

She scrambled and slithered about the bed, pulling and biting at the sheets until they were in ribbons, dozens of sheets were completely ruined For most of the time she was doubly incontinent Every few minutes, during the day and often through the night, she would let off a piercing wailing scream, rising to a crescendo and then fading out Early in this stage any approach by word or by touch, however gentle, would provoke outbursts of resistance and noise

During the long period of a hundred and thirty eight days, in spite of the patient's incessant restlessness and double incontinence, her skin remained healthy and intact This is a commentary on the devotion and pertinacity of the nurses There is little that militates more against recovery of damaged nervous tissue than infection, particularly that associated with decubitus ulceration and loss of serum-proteins

Gradually Mrs Moore became less restless and more purposive in her movements At times she would react favourably by gesture to the quietly spoken voice, when some kind of understanding or recognition would come into her eyes

As she slowly became more accessible and more amenable to examination we discovered that all her limbs were considerably paralysed and spastic, the left side being the worse The reflexes of all four limbs were those of an upper motor-neurone paralysis with hyperactive stretch reflexes and extensor plantar responses There was no evidence of a fracture dislocation of the cervical spine to explain the quadriplegia

On July 10 she was examined by Prof Martin Roth, who like us concluded that she was suffering not only from a brain-stem injury but also from hemispheral injuries He advised electro encephalography and this had to be done under anæsthesia (thiopentone because she was not yet sufficiently coöperative) Dr J N Walton and Miss B P Longley reported " intermittent but very prolonged discharges of high amplitude activity in all areas, these are sometimes more prominent on the right side The changes indicate a severe disturbance of the basal regulation mechanisms and are compatible with a lesion in the region of the upper mid brain or thalamus '

As the mental processes are awakening from injury, greater wisdom has to be shown in the exhibition of drugs for controlling restlessness, as a general rule the less given the better from the patient's point of view The months of August and September we regarded as constituting the transition stage between the phases of cerebral irritation and confusion

On Aug 10 the patient (cooperative but considerably confused) was examined for her pregnancy by Mr Linton Snaith, who estimated it at about 20 weeks Radiography on Aug 30 showed a fœtal skeleton of about 20-22 weeks Mr Snaith agreed that if possible the baby should be born by the natural route

At this stage, in August, the patient was doubly incontinent It was not until Oct 3 that she successfully used a bedpan and not until Oct 21 that she became completely continent of urine and fæces

During August she began definitely to speak, though she had uttered occasional words many weeks before this By the end of September she was repeatedly muttering short sentences such as " I love my Mummy " It is very doubtful whether, by the end of September, she was actually recognising her mother or her husband, who were constant visitors Perseveration of simple sentences spoken in a baby voice became an outstanding feature of the next weeks The perseveration possibly pointed to a lesion in the speech centre So far as we could judge, insight was very superficial during August and September, but in other ways there was definite improvement

Stage of Confusion

In October Mrs Moore unequivocably recognised her husband and gave him a proper kind of welcome

Formal psychometric testings were made on Nov 6, Jan 11, and March 1 by Mr R F Garside, of the department of psychological medicine in the University of Durham, using verbal tests, the picture completion test of the Wechsler Bellevue Scale, and Raven's Progressive Matrices On Nov 6 the patient had an I Q of 55 and a mental age of 6½ years, and on Jan 11 an I Q of 55 and a mental age of 7½ years During the early part of her pregnancy she had no insight into her condition Towards the end of gestation, however, she appeared to realise what was about to happen

Labour

On Nov 17 she went into labour and was transferred to the maternity department at 10 30 P M

By midnight definite contractions were evident, and thereafter she made rapid progress in the first stage of labour She proved to be most coöperative As soon as labour was well established, pethidine 100 mg was given to prevent undue excitement No other analgesic was necessary, and at no time did she manifest any real discomfort A healthy and perfectly formed boy was born at 4 A M on Nov 18

Mother and Child

Before the birth Mrs Moore kept asking when the baby would come When her newborn baby was handed to her, she immediately took hold of him with many expressions of delight She always held her baby in an experienced manner and looked forward to the times of breast feeding, which she managed perfectly

On Nov 26, while still in the maternity department, she had a generalised epileptiform convulsion and was unconscious for three minutes and deeply confused for half an hour There have been no further epileptic seizures She was sorry when the baby was sent to her aunt's in Leeds on Jan 1 but understood when it was explained that her mother, who lived in Newcastle, could only look after her son, aged 2, and it was necessary to get the child into the fresh air and away from a busy ward Mrs Moore is devoted to both children Her aunt writes regularly about the baby's progress, and Mrs Moore replies in her own handwriting and composition

Present State

Physical

Her general health is excellent Since her recovery from the acute stages of her illness she has virtually had no infection The contused contaminated wound on the left side of the scalp healed with hardly any inflammation Her smell, taste, hearing, and seeing are normal

Movements, tone, power, and coordination of her arms are normal, but both legs remain considerably paralysed Lying in bed she can lift each limb from the bed, bend the knee, and waggle the toes, but these movements are slow and tremulous With a walking cage she can support herself and make a few shuffling steps with each leg

Walking exercises were first started on Feb 11, each day there is some improvement, and with practice we expect further improvement because the difficulty in locomotion appears to be partly due to apraxia—i e, not knowing what to do—rather than entirely to paralysis and lack of coordination She can easily propel herself about the ward in a wheel chair

Mr J V Todd, our senior orthopædic surgeon, has supervised the problems arising from locomotion and lengthened the right tendo Achillis because of contraction

The patient's appearance is pleasant, and she keeps herself tidy and neat

Mental

Memory —Retrograde amnesia a few weeks ago was almost complete Today, March 25, 1957, there is definite evidence that glimmers of her earlier life are coming through, and we have, on this and past experience, reason to hope that the period of retrograde amnesia will substantially shorten Memory for present events is satisfactory, for example, Mrs Moore can remember what she had for breakfast, whether or not she bought a paper earlier in the day, and what transactions she had to make for it

If the temporal lobes of the brain are the chief site of memory, they must have been damaged but not irretrievably destroyed, because the patient can remember some things Without the background of the memory of previous experience the remaining intellect will be short of those ingredients of which depth of thinking is made The first indubitable sign of return of memory was a visual one—i e, recognition of a familiar face

Speech —Her ability to speak, though much impaired, is now approaching normal Her chief defect is a nominal aphasia—e g, she will recognise an apple, peel it, and eat it, but cannot easily find its name When the name is mentioned to her, she nods her head in assent and smiles She can read quite freely from a newspaper She can write a letter, but in the more involved parts of construction she needs help She writes accurately and quickly from dictation

One of the outstanding features nowadays is her tendency to go on repeating sentences such as "I love my baby," and often these are included in a wrong context Her word centre at one time was greatly disturbed, giving the impression that she was rather more severely demented than she actually was Of course, it has to be realised that intellect and speech are very closely interwoven She speaks in a high-pitched childish voice which in some ways gives the wrong impression and suggests that she is a little more simple than she really is The report of Miss M E Morley, our speech therapist, is as follows

" *Articulation* is normal There is no sign of any dysarthria or apraxia

" *Language* —When I first saw Mrs Moore on Dec 30, her language was childish and she used short phrases What she said was sensible, but there was a peculiar intonation in her speech resembling that of a spoilt child, and when she attempted to use longer phrases or became excited at all there was a clonic spasm, chiefly on the initial consonant in words involving a rapid repetition of the initial consonant sound Since then her language has continued to improve very slowly She uses longer phrases, but the stammer is still in evidence and now frequently involves the initial syllables in words At times there appears to be more tension in this spasm than there was initially This may be comparable to the transient stammer of childhood which she may outgrow, although it is possible that it may become worse if she becomes aware of it and attempts to inhibit it It may become increasingly worse as she uses longer phrases

Comprehension appears to be adequate There was no visual agnosia when I first saw her in December Auditory verbal comprehension was normal as were also oral reading and comprehension for reading, so far as I could assess it "

Accessibility —Within the limits of her immediate surroundings of time and space she is perfectly accessible Any faults that there may be are due to faults in memory

Awareness —She is perfectly aware of her surroundings She knows that she is in hospital is much interested in the activities of the ward speaks freely with the other patients, and knows the day of the week and the time of day She can add single figures, use money, and give change In the morning she buys her own papers and knick-knacks and carries out accurately the monetary details concerned

Insight —It is her insight that is superficial, indeed it is her mental shallowness that is her main incapacity at present She recognises her husband, mother, and eldest child (the baby is away in Leeds), but her reactions to them are entirely superficial She knows that she had an accident but does not appreciate its significance though here again a glimmer of comprehension is beginning to appear Her state is that commonly seen in the early stages after a fairly radical prefrontal leucotomy

Emotionally she is labile, extroverted, trusting, and affectionate She is not, however, without a sense of humour—when asked which was her weak leg she replied that she did not think much of either of them

Psychological report —On March 1 Mr Garside reported

" On this occasion I gave Form II of the Wechsler Bellevue Scale Her Verbal Scale I Q of 65 is slightly higher than that obtained before but her Performance Scale I Q of 66 is just about the same Her score was also the same on the Raven's Progressive Matrices Test

Her test scatter still suggests that her mental processes which involve knowledge and experience are more impaired than those which are concerned with the solution of new problems It therefore seems that her relearning might be helped by some kind of appropriate tuition "

Electro encephalographic report —A report on Feb 28 stated " The record is again within the limits of normal variation, and there is a stable alpha rhythm at 10–11 cycles per second "

Progress —Since the above summary was written further improvement has taken place, particularly as regards insight

Comments

Cooling

The value and the depths of cooling necessary for certain types of operation on the heart and head are now becoming known Less, however, is known about the optimum limits of depth and duration of cooling for direct therapeutic purposes When used therapeutically the objects of cooling are threefold

(1) *Antipyretic* —The object here is to combat excessive rises of temperature that are harmful and possibly lethal Our experiments have shown that lowered temperatures of 30–34°C can be safely maintained for seven days without inflicting serious damage on vital tissues

(2) *Protective* —The object in protective therapy is to tide tissues over from the deleterious effects of injury and infection and from excessive reactions of the body to the damaging agent while natural processes of repair or special medicaments—e g, antibiotics—have time to act We judge that, for protective purposes, the temperature will have to be 28–32°C How long such degrees of cooling can be maintained with safety we do not yet know On the other hand, experience gained at operation has shown that they can be maintained safely for twenty four hours

(3) *Curative* —Here the object is to lower a patient's temperature to such a degree that the injuring agent is destroyed while the normal cells of the body are left unharmed Such therapy may be the future means of destroying certain forms of bacteria and malignant cells This type of treatment will probably require temperatures well below the fairly safe figure of 28°C

Pregnancy

This is the first opportunity we have had in our Newcastle clinic of observing the effect of a head injury on a pregnancy established for 3 months or less

The fœtus continued to develop normally although much of the mother's nervous system was out of action while the fœtal brain was developing

No doubt the patterns of the future are laid down at the moment when the mother's ovum and father's spermatozoon unite and are little influenced by the mother's nervous system during growth The mother affords shelter and nutriment Any fault or disease in the maternal nutriment can, of course very seriously affect the child—e g, the toxæmia of rubella is likely to cause mental defect The effects, however, of injury to the head, or indeed the other parts of the mother's body, are not passed on to the child, and mothers can be firmly reassured on this point

Uterine injuries, of course, can harm the child directly, but this is a totally different matter

Seat of Unconsciousness

Because some of the evidence in the acute stages of injury pointed to damage of the upper brain-stem, it would be wrong to argue too closely that the clinical happenings described above were due to paralysis and gradual awakening of upper-brain-stem function Indeed, there is much to suggest that the post traumatic picture of the clinical improvement points more to recovery of hemispheral than of upper-brain stem function Indeed, the sparing of the arms and paralysis of the legs can be more easily explained on hemispheral than on upper-brain-stem damage, as can the dysphasia There is now some evidence forthcoming from the neurological world that the highest level of neural integration lies somewhere within the upper brain-stem area

None the less, should this hypothesis prove true, the integrative action of the brain stem must depend on information that comes to it from elsewhere It is likely that paralysis of the cerebral hemispheres will remove sources of information that are essential for proper functioning of processes of integration and give the erroneous impression that the brain-stem has been primarily concussed and not affected secondarily by paralysis of the cerebral hemispheres, as no doubt it commonly is We are far from convinced that the loss of consciousness in most head injuries is due to brain stem damage

It has been our experience that a head injury of the closed variety rarely leaves the patient seriously demented permanently No tissue in the body seems to react more wisely to injury or infection than does the brain tissue It is this knowledge that encouraged us from the outset in this difficult case

Finally, though the treatment of the patient with a serious head injury calls for many surgical disciplines, what success we have had in this case is due largely to the skill, devotion, and pertinacity of our nurses

Our thanks are due to Miss F E Shaw matron of the Newcastle General Hospital, Mr K C Booker, group secretary of Newcastle upon Tyne Hospital Management Committee, and Mr J B Duckworth our hospital secretary, for their continued help and encouragement

KERATO-ACANTHOMA OF LOWER-LIP RED MARGIN

C Howard Whittle
M A, M D Camb, F R C P
PHYSICIAN, SKIN DEPARTMENT, UNITED CAMBRIDGE HOSPITALS AND ASSOCIATE LECTURER, UNIVERSITY OF CAMBRIDGE

Roy A Davis
M B Lond
REGISTRAR SKIN DEPARTMENT UNITED CAMBRIDGE HOSPITALS

Kerato acanthoma and molluscum sebaceum are the names given to a benign self healing tumour of the skin which grows rapidly for six weeks or more, reaches a maximum of 1-3 cm in diameter, and then slowly regresses, leaving after several weeks a flat atrophic area with a crinkled and slightly hypertrophic edge Without spontaneous regression the diagnosis remains in doubt While it is growing a kerato acanthoma so closely resembles a well differentiated squamous carcinoma, both clinically and histologically, that in the past many lesions have undoubtedly been diagnosed and treated as such

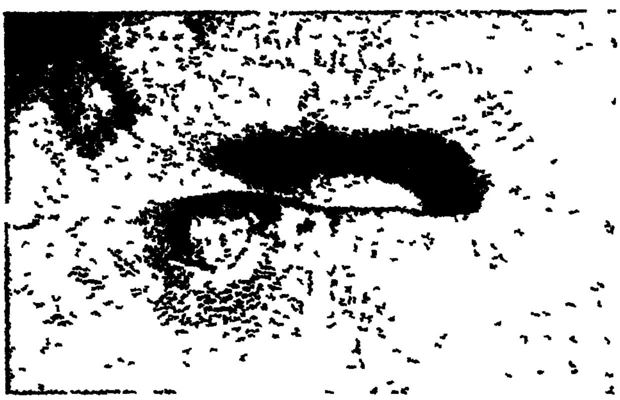

Fig 1—At 6 weeks

This benign tumour is fairly common, and occurs in Great Britain about half as frequently as squamous carcinoma (Rook 1956) MacCormac and Scarff (1936) were the first in this country to recognise and describe the lesion, which they called molluscum sebaceum Other names such as "molluscum pseudo carcinomatosum" (*Lancet* 1953) have been suggested Since Rook and Whimster (1950), at Dowling's suggestion, thoroughly investigated the condition, there have been many reports testifying to its widespread prevalence—e g, Baumann and Lennox (1954), Beare (1953), Binkley and Johnson (1955), Finley (1954), *Lancet* (1953), Levy et al (1954), Liban and Lennox (1955), Musso and Gordon (1950), Russell and Calnan (1952), Whittle and Lyell (1952), Wigley and Pettit (1952), and Zoon et al (1954)

The reason for publishing one case is that kerato-acanthoma on the red margin of the lip has not hitherto been seen, or at least *reported*, in Great Britain, and of 181 lesions described in the literature (Rook 1956) none started on the lip There have been one or two lesions on this site mentioned in foreign journals—e g, Ereaux et al (1955), Rabut and Hewitt (1954), and Spier and Thies (1956)—but this type of lip tumour has apparently been overlooked

We believe that a more general awareness among clinicians of its incidence will lead to the discovery of many such tumours on the lip, perhaps as many as on the rest of the skin Kerato acanthoma is rare on clothed parts—only 3% of the lesions recorded (Rook 1956)—and the same agents that affect the exposed skin also affect the lip Outdoor workers are those most likely to develop kerato acanthoma, especially if they have bright complexions and fair hair Such skins are readily irritated by strong sun and harsh weather and, after years of exposure, commonly show keratoses on the face and backs of the hands

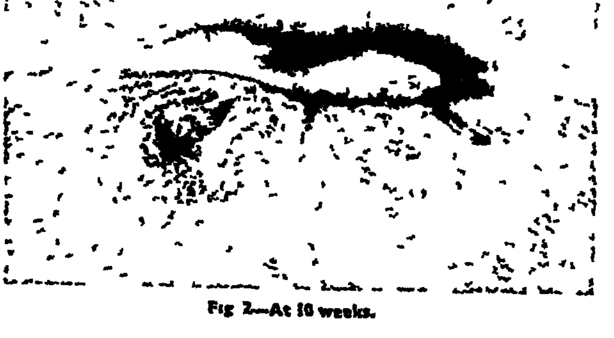

Fig 2—At 10 weeks.

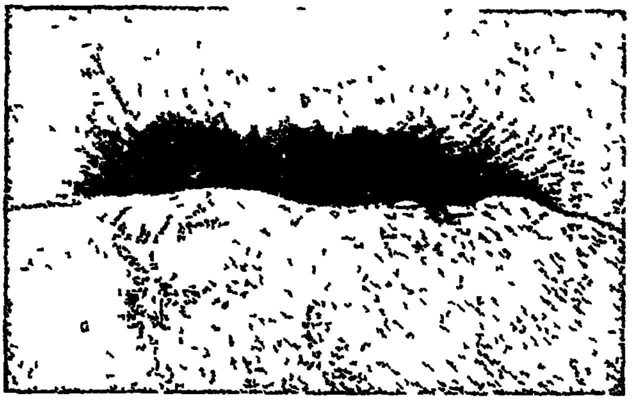

Fig 3—At 19 weeks

Case-report

A farm worker, aged 48, sandy-haired and ruddy, showed such keratoses In May, 1956, he noticed a spot on his lower lip, on the site of a "cold sore," which grew rapidly and presented after six weeks the button like tumour depicted, measuring 1 cm in diameter, with a large central keratotic plug (fig 1) Four weeks later it had flattened, and the centre plug had been shed, leaving a granulomatous crater (fig 2) At nineteen weeks from the onset the lesion had further flattened, the crater had healed and was hardly visible, and the infiltration had almost gone (fig 3) Diffuse roughening and scaling of the whole of the lower lip, also shown in the photograph, have been present for months At no stage has there been any palpable enlarged lymph node, and the only treatment was the local application of hydrocortisone ointment and antibiotics Biopsy at six weeks showed an appearance consistent with the diagnosis of kerato acanthoma, but the possibility of squamous carcinoma could not be excluded The subsequent course appears to have ruled out the more malignant alternative, but the patient is still under close supervision (Postscript, May, 1957 The lip is now normal)

Summary

Kerato-acanthoma on the red margin of the lip is apparently unknown in Great Britain

A case showing spontaneous regression is described

Awareness of its possibility and closer examination of lip tumours generally may well reveal a frequency on the lip comparable to the known frequency of kerato acanthoma on areas of skin exposed to light

Preliminary Communication

CORRELATION OF SERUM-MAGNESIUM AND SERUM-CHOLESTEROL LEVELS IN SOUTH AFRICAN BANTU AND EUROPEAN SUBJECTS

IN a recent publication from this institute[1] it was shown that in many cases of coronary heart disease a dramatic clinical improvement followed parenteral administration of magnesium sulphate Two groups were treated

(*a*) Patients who were first seen during an acute attack of coronary thrombosis or coronary insufficiency

(*b*) Patients who had recently recovered from an attack of coronary thrombosis or who were suffering from angina of effort

Abnormal lipoprotein patterns rapidly reverted to normal in many of the cases

In those areas of Africa in which reliable information is available, coronary thrombosis is reported to be uncommon in Africans[2]

In Johannesburg the disease is very rare among the Bantu Thus Becker,[3] in 352 necropsies on predominantly Bantu people over the age of 50, attributed only 1 death to coronary thrombosis, and Higginson and Pepler,[4] in 523 unselected necropsies at a Johannesburg non European hospital, found an incidence of only 1 6% and 3 0% respectively of coronary occlusion in the 41–60 and 61–80 age groups These figures contrast with an incidence of 12 8% and 13 3% found in similar age groups by Gordon et al[5] in 3400 post mortems at the Massachusetts General Hospital

Serum cholesterol levels are lower in the African than in the European

The mean serum cholesterol level of newborn Bantu and European babies is virtually identical One of us found that, at the age of 21–30, 70 healthy South African Europeans of both sexes had a mean cholesterol level of 215 mg per 100 ml, whilst in 89 African nurses of a similar age group the corresponding level was 174 mg A group of male Bechuana Africans had a mean cholesterol level of 156 mg[6] Walker and Arvidsson[7] have shown that in the Bantu the rise of serum cholesterol levels with age is slight compared with the steep rise in Europeans

In view of our striking results with magnesium sulphate therapy in coronary thrombosis and the low cholesterol levels and low incidence of coronary occlusion in the Bantu, we decided to investigate the serum magnesium level in European and Bantu groups, and to find out whether it was correlated with the serum cholesterol level

Serum magnesium levels were estimated by the method of Orange and Rhein,[8] and cholesterol determinations were carried out by Sperry and Webb's modification of the Schoenheimer and Sperry technique[9]

Serum-magnesium levels were determined on 47 normal European and 53 normal Bantu (all 25–45 years) The results were

Subjects	*Serum magnesium level (mg per 100 ml)*
European	Range 1 52–2 50 Mean 1 82 (S D 0 15)
Bantu	Range 1 85–2 55 Mean 2 11 (S D 0 10)

P = < 0 005—i e, a highly significant increase in serum magnesium levels in the Bantu as compared with the Europeans

---

8 Orange M Rhein H C *J biol Chem* 1951 189 379
9 Sperry W M Webb M *Ibid* 1950 187 97

Serum magnesium levels were then correlated with serum cholesterol levels in a group of Europeans, with the following results:

Serum-cholesterol level (mg. per 100 ml.)	Serum magnesium level (mg. per 100 ml.)	"P" factor (as compared with the mean serum magnesium level in normal European subjects)
121–197 (15 cases) Mean level 170	Range 1·76–2·40 Mean 2·06 (S.D. 0·15)	< 0·005 Highly significant increase
202–250 (22 cases) Mean level 226	Range 1·65–2·40 Mean 1·95 (S.D. 0·20)	0·3 Not significant
255–294 (12 cases) Mean level 273	Range 1·78–2·10 Mean 1·95 (S.D. 0·09)	0·3 Not significant
310–389 (21 cases) Mean level 348	Range 1·27–2·15 Mean 1·76 (S.D. 0·18)	< 0·005 Highly significant decrease
402–586 (10 cases) Mean level 470	Range 1·25–2·10 Mean 1·71 (S.D. 0·25)	< 0·005 Highly significant decrease

These results show (1) that the serum-magnesium level is significantly higher in the non-European than in the European, and (2) that a definite correlation exists between serum-magnesium and serum-cholesterol levels. Normal serum-magnesium levels are found in the normocholesterolæmic group (cholesterol 200–300 mg. per 100 ml.). Where the serum-cholesterol content is low (120–197 mg.) the magnesium content is significantly increased, and is almost identical with the figure found in the non-European. The hypercholesterolæmic group (cholesterol 310–586 mg.) shows a significantly lowered magnesium level when compared with the normal European and a very highly significantly lowered level when compared with the normal non-European.

These findings suggest that the part played by magnesium in diet and nutrition requires further study. The possible rôle of this element in cholesterol metabolism, and indirectly perhaps in atherogenesis, has not been fully appreciated, studied, or recognised.

A COMBINED BED-CRADLE AND FOOT-SUPPORT FOR USE WITH LEG TRACTION

WHEN weight-extension is used on a leg, there is a tendency for the patient to be pulled down the bed. To correct his position he pulls on the handle suspended from the Balkan beam and obtains counter-pressure by pushing the back of his heel against the bed. The skin in the part thus subjected to pressure is thin, and often a sore develops on it despite all nursing care. The combined foot-board and bed-cradle here described was evolved as a means of taking the counter-pressure on the thick skin of the sole and heel, which is well adapted to weight-bearing (fig. 1).

The bed-cradle (fig. 2) (24 × 28 × 18 in., 61 × 71 × 46 cm.) is made up of $^5/_8$ in. (1·5 cm.) conduit tubing, to which are welded four metal strips 18 × $1^1/_4$ × $^3/_{16}$ in. (46 × 3 × 0·5 cm.). In each strip there are fourteen holes, $1^1/_4$ in. (3 cm.) apart. The strips are so fitted that the holes in the upper ones are immediately above those in the lower ones.

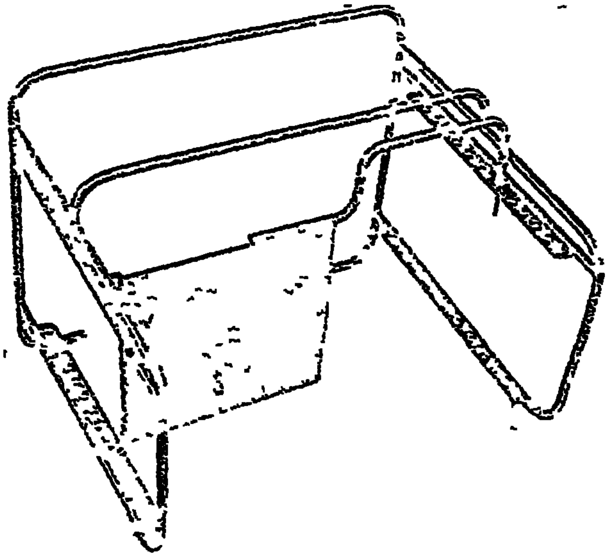

Fig. 2

The foot-support consists of a board $13^1/_2$ × 12 × $^1/_2$ in. (34 × 30·5 × 1 cm.), to three corners of which are attached brackets which can be dropped into the holes in the steel strips. The series of holes makes the appliance adjustable for patients of varying heights. To allow for extension, the board is only half the width of the cradle. It can be used for either leg by lifting it out of place and reversing it.

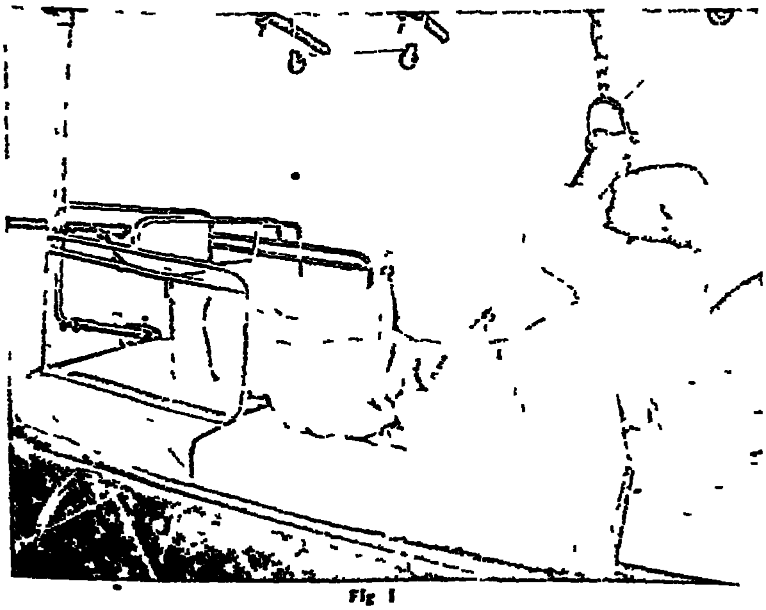

Fig. 1

The cost of the materials was about *17s. 6d.* The device can be made in one and a half days, so with labour the total cost is *£3 7s. 6d.*

I am very grateful to the engineer (Mr. E. G. Ingram) and the fitter (Mr. E. T. Powell) of the Royal Buckinghamshire Hospital, Aylesbury, who not only made the apparatus but provided several useful suggestions. I am indebted to the department of clinical photography, Stoke Mandeville Hospital, Aylesbury, for the photographs.

ROYAL SOCIETY OF MEDICINE

Chronic Relapsing Pancreatitis

A MEETING of the section of surgery was held on May 1, with Mr ERIC CROOK in the chair

Dr H DOUBILET (New York) emphasised the physiological unity of the biliary and pancreatic system In his experience of some 500 cases of relapsing pancreatitis treated by sphincterotomy, the two duct systems always terminated in a single common opening into the duodenum Recurrent pancreatitis was caused by reflux of bile up the pancreatic ducts as a result of spasm of the muscle surrounding this common channel, and could be cured by division of this muscle Such spasm could be caused by the local application of hydrochloric acid, and had been shown to cause reflux the reflux of bile concentrated by the gall-bladder was particularly deleterious, and accordingly cholecystectomy could be effective even if the gall-bladder was normal Clinically spasm of this sphincteric muscle resulted from pain, emotional stimuli, and distension of the common bile-duct Morphine caused similar spasm, and should not be used to relieve pain in pancreatitis

Dr Doubilet described his technique of catheterisation of the pancreatic duct at the time of operation, which enabled contrast medium to be injected into the duct system as long as the tube remained in situ When the disease was in a quiescent phase such X-ray examination showed a dilated tortuous duct and main branches, but when active inflammation was present there was an alteration in the permeability of the duct epithelium allowing the dye to suffuse out and opacify the affected part of the gland There was no evidence that pancreatitis was caused by obstruction of the pancreatic duct itself Pain in pancreatitis was due partly to increased pressure in the pancreatic duct system, and partly to chemical irritation and inflammation of the tissues

As the pancreas was a retroperitoneal organ, rupture of the duct system would allow a highly irritant exudate to spread throughout the retroperitoneal space as well as within the peritoneal cavity Fibrosis consequent upon this exudate could obstruct the transverse and descending colon Alternatively the exudate may collect locally to form a pseudocyst, and Dr Doubilet showed radiographs demonstrating that these cysts communicated with the pancreatic duct system, and could be cured by adequate drainage by sphincterotomy

Relapsing pancreatitis could almost always be cured by sphincterotomy with division of the muscle surrounding the common opening of the biliary and pancreatic systems If there were calculi in the main duct they should be removed if this was not possible, caudal pancreaticojejunostomy might infrequently be indicated After a properly performed sphincterotomy, with division of the papilla for 8–10 mm proximally from its opening, reflux from the duodenum did not occur, being prevented by the duodenal muscle coat, but reflux from the common bile duct was no longer possible, as could be shown by testing with hydrochloric acid The regenerative capacity of the pancreas was great, and after sphincterotomy a severely damaged pancreas could return almost to normal, as shown by secretin tests and histological studies But until regeneration was complete the pancreas was peculiarly and specifically sensitive to alcohol and fats, which could provoke further attacks Accordingly the patient must be warned to avoid these substances for 6–18 months after operation

Dr Doubilet showed a film taken with an image-intensifier illustrating the function of the sphincteric mechanism around the opening of the pancreatic and biliary ducts The films were taken in a patient with a cholecystostomy tube, which was used to inject radio-opaque fluid Reflux up the pancreatic duct was clearly seen following painful stimuli and distension of the common bile duct after sphincterotomy this reflux could no longer be produced The film also illustrated dramatically the churning mixing action of the duodenum after the introduction of fat, in contrast to its relative inactivity when carbohydrate and protein were injected

Mr RODNEY SMITH pointed out that relapsing pancreatitis appeared to be less common in Great Britain than in America, and the difference in incidence was not entirely explained by a failure to recognise the disease in this country He agreed that, in his experience, relapsing pancreatitis was nearly always associated with biliary reflux, but that did not mean that every isolated instance of acute pancreatitis was due to this cause Further, it was a common observation from routine postoperative cholangiography that minor degrees of reflux often occurred without precipitating pancreatitis He suggested that acute pancreatitis probably caused changes in the duct epithelium, and that thereafter if recurrent biliary reflux occurred the patient would suffer recurrent attacks of pancreatitis

Mr Rodney Smith showed cine cholangiograms illustrating pancreatic reflux There was no doubt that this reflux occurred in relapsing pancreatitis, and that its prevention was important This was most simply done by the operation of sphincterotomy, which carried a low risk and was usually the operation of choice Nevertheless on occasion other operations might be required Sometimes there was very severe œdema and fibrosis, with a rigid, thickened duodenum and an obstructed bile duct in such cases biliary diversion by cholecystoduodenostomy or cholecystojejunostomy might be the operation of choice If there was heavy calcification of the pancreas with a mass of calculi blocking the main duct, the distal pancreas should be excised, the duct cleared of stones and then anastomosed to a Roux loop of jejunum (caudal pancreaticojejunostomy) Division of the splanchnic nerves had been recommended for the relief of the pain, and there seem no doubt that this operation did relieve the pain, but cholangiographic studies showed that it did not prevent reflux and it should accordingly be regarded as an illogical form of treatment Excision of the head of the pancreas, pancreatoduodenectomy, also had some place in treatment and good results had been obtained, but owing to the extensive fibrosis binding the pancreas to the portal vein and adjacent structures, this was both a difficult and dangerous operation, which should not be undertaken unless there were categorical indications

Dr W I CARD (Edinburgh) said that, as seen by the physician, the condition usually presented either as a problem of undiagnosed abdominal pain or of steatorrhœa with nutritional deficiency, pain being more prominent early in the disease and nutritional changes late Pain was due to a rise of pressure in the pancreatic duct system, and could sometimes be provoked by giving secretin and morphine, after which it could be relieved by amyl nitrite After the operation of sphincterotomy secretin and morphine no longer precipitated pain

The pain of pancreatic disease might often be difficult to differentiate from that of biliary origin, but it tended to last longer At times ulcers in the second part of the duodenum gave rise to pain closely simulating pancreatitis, as might peri-Vaterine duodenal diverticula An acute exacerbation could usually be managed by gastric suction and the administration of pethidine or morphine, atropine, and glyceryl trinitrate

In all cases of pancreatic disease pancreatic function tests, if properly performed, were undoubtedly useful Secretin by itself did not stimulate pancreatic enzyme production, and as the output of amylase seemed the most sensitive indication of pancreatic function, better results were obtained by a combined secretin and pancreozymin test, this latter hormone stimulating the pancreas to secrete amylase Dr Card illustrated the results obtained by this test in several cases of chronic pancreatitis, as compared with the normal The glucose-tolerance test was invaluable in differentiating pancreatic from intestinal steatorrhœa In the treatment of pancreatic insufficiency, pancreatin by mouth was often successful

AMERICAN PROCTOLOGIC SOCIETY

THE society met in New Orleans under the presidency of Dr **RUFUS C ALLEY** (Lexington, Kentucky) on April 24-27

Tropical Diseases

Dr **JOHN McGIVNEY** (Galveston, Texas) described the perianal subcutaneous lesions associated with the penetration of the hookworm larva, *Ankylostoma braziliense* from moist sand after previous deposition in ova from from the excreta of cats and dogs, these were treatable with carbon-dioxide snow or ethyl chloride, chloroquinone diphosphate being given systemically

Dr **PORFIRIO M RECIO** (Manila, Philippines) described the lesions which result from infestation with *Schistosoma japonicum*, prevalent in the Philippines, large [illegible] liver, and rarely brain are affected The colonic lesions pass through hyperæmic, suppurative, ulcerative and adenomatous and granulomatous stages until, as with *hæmatobium* in the bladder, carcinoma supervenes There is no effective treatment after penetration of the parasite excision or resection of the colon is necessary for the granulomatous or carcinomatous degenerations, and the opportunity should be taken to remove the appendix since embolism of its blood-supply by ova frequently produces gangrene

Colonic Volvulus

Dr **IRVING A. LEVIN** (New Orleans Louisiana) gave an account of 74 cases of colonic volvulus admitted to hospital between 1945 and 1955 There were 11 deaths (14 8%), the sigmoid was involved in 63 cases (10 deaths), and the cæcum in 11 cases (1 death) The correct diagnosis was made before laparotomy in the cæcal form only once, there was a tendency to recurrence after simple detorsion and fixation, so right hemicolectomy was advised For the sigmoid volvulus proctoscopic reduction by the passage of a deflating rubber tube was frequently effective, and this was followed by sigmoid resection to obviate recurrence There was little danger of perforation of the bowel by the tube there being only 2 instances of this in 182 reported proctologic reductions, but care must be taken to ensure that gangrene of the bowel was not present after successful non-operative reduction

Diverticulitis

Dr **RICHARD L BUCK** (New Orleans, Louisiana) reported 256 cases of diverticulosis and diverticulitis out of a total of 327,871 admissions to the Charity Hospital Louisiana, in a six-year period 131 were uncomplicated and required no surgery In cases complicated by perforation or obstruction there was a mortality of 50% in only 1 case was the bladder involved 75% of the patients were over 60 years old, pain was the commonest symptom, with bleeding second in order of frequency

Rectal Procidentia

Dr **NORMAN D NIGRO** (Detroit Michigan) described an operation for cure of rectal procidentia by means of a fascial sling reinforcing the atrophic puborectalis muscle fixed to the pubes in front and passing behind the rectum at its junction with the anus, operative approach was achieved by removing the coccyx and passing the sling forwards to be attached to the pubes through a retropubic approach Dr **A F CASTRO** (Washington D C) preferred to treat rectal procidentia by anterior resection of the redundant bowel, and had had no recurrences after this procedure

Anorectal Surgery

After excision of piles or fissure, Dr **V R MANNING** Philadelphia Pa) favours covering the raw area with a sliding graft of perianal skin and Dr **CHARLES E POPE** Evanston Illinois) direct suture after lateral relieving incisions

Dr **JAMES A FERGUSON** (Grand Rapids Michigan) described a method of hæmorrhoidectomy with complete closure of all wounds with simple catgut suture, undertaken in 8080 patients with few complications and little morbidity

Dr **M J ANDERSON** (Rochester Minnesota) had studied perianal hidradenitis suppurativa—an intractable condition often associated with acne and sometimes mistaken for pilonidal sinus and simple fistula-in-ano—and demonstrated that apocrine glands were only secondarily involved and could not certainly be regarded as the source of the condition, eccrine glands also became affected as did hair-follicles and sebaceous glands Malignant change complicated long-standing cases

Polyps and Cancer of Colon and Rectum

Dr **W A FAUSTER** (Minneapolis, Minnesota) did not consider the "second look" procedure reasonable as a routine, though possibly useful as an experiment, nor did he think that it will prove to have been worth while

Dr **RUPERT TURNBULL** (Cleveland, Ohio) reported that in a series of 86 cases of colorectal polyps locally removed through the colon, only 3 patients had died of cancer he felt that, since pathologists reported malignant change in only 10% of apparently benign polyps, radical surgery was not necessary and that this was borne out by the facts presented

Dr **S J FIGIEL** (Detroit, Michigan) advocated radiodiagnosis of colonic polyps by means of a barium enema, using 120 kV with compression over the area of bowel under study

Dr **MERRILL O HINES** (New Orleans, Louisiana) emphasised the fluid and electrolyte loss from villous tumours, so great might this be that patients with villous tumours were sometimes admitted in severe electrolyte depletion, 30% of these lesions showed malignant change

Ulcerative Colitis

Mr **STANLEY AYLETT** (London) advocated preservation of the rectum in the surgical treatment of ulcerative colitis he reported on 54 patients submitted to ileorectal anastomosis

Mr **B N BROOKE** (Birmingham, England) discussed the need for electrolyte therapy to replace loss from an ileostomy approximately 300 m eq per litre was excreted from the ileostomy and was the additional sodium requirement in the immediate postoperative period this fell to 150 m eq per litre in the established case Potassium loss was a preoperative problem which ileostomy tended to correct Cortisone appeared to conserve sodium, as expected, while potassium concentration in the ileostomy fluid increased, but the total excretion from ileostomy and urine was not increased since the volume of excretion from both sources was reduced by cortisone

Dr **GEORGE LUMB** (Memphis, Tennessee) described biopsy studies of the rectum from which he concluded that though quiescence of the disease might be manifest histologically it was impossible to predict from biopsy specimens how long a remission would persist

Britain's National Health Service

Mr **A LAWRENCE ABEL**, who at the beginning of the meeting had received the honour of free citizenship of the town of New Orleans delivered the Mathews oration Dr Mathews had been the first surgeon to undertake proctological practice, thus founding the specialty of proctology, he had advised young men to travel widely and then set up practice in a town of their choice Mr Abel felt that this would still be good advice to young men anywhere except in Great Britain today He then developed the thesis of his oration by enumerating the dissatisfactions of certain elements of the medical profession in this country and indicted the Government for what he regarded as failures in "socialised medicine"

Reviews of Books

A Manual of Human Anatomy

J T AITKEN, M D reader in anatomy, University College, London, G CAUSEY, M B, F R C S, professor of anatomy, Royal College of Surgeons London, J JOSEPH, M D, M R C O G, reader in anatomy, Guy's Hospital Medical School, London, D A SHOLL, B SC, reader in anatomy, University College, London, J Z YOUNG, M A, F R S, professor of anatomy, University College, London Edinburgh and London E & S Livingstone 1956 and 1957 Vol 1, *Thorax and Upper Limb*, pp 162, 14*s*, Vol 2, *Head and Neck*, pp 180, 16*s*, Vol 3, *Abdomen and Pelvis*, pp 127, 12*s* 6*d*, Vol 4, *Lower Limb*, pp 117, 12*s* 6*d*, Vol 5, *Central Nervous System*, pp 128, 12*s* 6*d*

ACCORDING to a preface, this work aims "to give the student of human anatomy a method of dissecting the body and to guide him as to the extent of the knowledge expected of him in the second medical examination" Development is occasionally considered The volumes are well produced, with plastic covers and a ring-binding which has advantages in the dissecting-room, where they stay open comfortably at any desired page The illustrations are diagrammatic, and colour is freely used At the end of each manual is a suggested scheme for practical classes in osteology and surface anatomy The text is clearly written, and much anatomical detail has been suppressed in favour of brief discussions on the functional aspects These functional sections are a welcome feature which should do much to preserve the student's initial enthusiasm Simplified anatomy books are now in the ascendant, and apparently the examiners are satisfied, is it too much to hope for a similar simplification of the textbooks in other preclinical subjects?

New Bases of Electrocardiography

DEMETRIO SODI-PALLARES, M D, chief of the department of electrocardiography at the National Institute of Cardiology of Mexico English translation by ROYALL M CALDER, M D, clinical professor of medicine, Graduate School, Baylor University London Henry Kimpton 1957 Pp 727 £6 15*s*

THE empirical accumulation of knowledge about the electrocardiogram, and its remarkable diagnostic accuracy in expert hands, tended to retard interest in the principles underlying its interpretation The introduction of unipolar leads and the extended use of chest leads have, however, encouraged clinicians to take the more rational view of electrocardiography, which the fundamental work, particularly of F N Wilson and his colleagues, has made possible Modern methods of calculating the electrical axis of the heart and of vector analysis have now brought electrocardiographic interpretation near to scientific exactitude, and much useful information has come from a study of the intracavitary potentials of the heart The time was clearly ripe for a postscript to Lewis's classic *Mechanism and Graphic Registration of the Heart Beat* Dr Sodi-Pallares's valuable book has now been effectively translated into English

The bases of electrocardiography are lucidly surveyed in introductory chapters on the principles of electricity and electrophysiology, and then applied to the major abnormalities of heart disease The initial chapters, though solid reading, are clear and reasonably easy to follow, and many clinician will be glad that the mathematical aspects have been relegate to an appendix The theoretical implications of the maj- abnormalities are minutely discussed, and the more important original work on each is critically and judicially reviewed The chapter on myocardial injury is particularly valuable and illuminates a number of clinical problems

The contributions from Sodi Pallares's laboratory includ important studies of the activation process of the heart b direct endocardial leads in dogs and intracavitary leads i man These are of the greatest interest particularly in relatio to the activation of the interventricular septum and th nature of bundle branch block Too many details of experimental procedure would clearly be inappropriate in a textbook, but one could wish to know more of the technica methods employed without necessarily having to consult th original papers The diagrams, though generally excellent are sometimes overcrowded and not clearly lettered

The book must be nearly indispensable to anyon seriously interested in electrocardiography

Allergic Dermatoses due to Physical Agents

Edited by RUDOLF L BAER, M D, assistant professor o clinical dermatology and syphilology, New York University Postgraduate Medical School Philadelphi and Montreal J B Lippincott London Pitma Medical Publishing 1957 Pp 110 24*s*

THIS book contains essays by the editor and six othe contributors (including Stephan Epstein and Stephe Rothman) which were previously published in th *American Practitioner* They are concerned with th theoretical and clinical aspects of skin changes produce by "allergic" responses to light, heat, cold, and traum in the sense of external pressure The book brings togethe helpful information on subjects which are badly discussed in most dermatological textbooks, and it wil interest others besides skin physicians and teachers Its value is enhanced by detailed bibliographies and a good index

---

Dorland's Illustrated Medical Dictionary (Philadelphi and London W B Saunders 1957 Pp 1598 87*s* 6*d*)—Dr W A Newman Dorland having died last year at the ripe age of 92 after editing 22 editions of *The American Illustrated Medical Dictionary*, this 23rd edition has been rechristened in his honour Apart from the addition of many new words there appear to be few changes The page size has been slightly enlarged to accommodate the newcomers, some names of plants and non medical words—e g, *abattoir*—have been dropped, and the article on medical etymology has been moved from the front to the back of the book As a sign of modern spoon feeding, after having had 22 editions withou such a section, we now have one of 4 pages entitled Notes on Use of This Dictionary Some errors in the 22nd edition—e g, *etiocholanolone* and the obvious one under *porphobilinogen*—have been corrected This excellent new edition will be heartily welcomed by those acquainted with its predecessors and can be thoroughly recommended to those to whom it is being introduced for the first time

Public Health and Social Services (4th ed London Edward Arnold 1957 Pp 160 9*s*)—From being an elementary textbook to teach pupil midwives how they could expect to fit into the pattern of the personal health services, this little book has changed during its four editions into a more comprehensive outline of our wider social services The authors are Dr Dennis Geffen, Mr Leslie Farrer Brown and Dr M D Warren It is a handy size for a nurse's pocket, but it cannot do much more than point the way towards more specialised guides

The Therapy of Bronchial Asthma (*Proceedings of the International Round Table Friendship Meeting of Allergologists* Leiden H E Stenfert Kroese N V 1956 Pp 354 50*s*)—The treatments discussed in this report of a symposium held in 1955 range from surgery to thermal spas The speakers came from Europe Israel and the United States, this country is represented by Dr A W Frankland, Dr Denis Leigh, Dr Kate Maunsell Dr R S B Pearson, and Dr D A Williams The proceedings are published in English, save for one paper in French, and they are edited by Mr Dr W J Quarles Van Ufford

THE LANCET

LONDON SATURDAY MAY 18, 1957

Surgical Treatment of Ischæmic Heart-disease

In historical order the surgical treatment of ischæmic heart-disease takes precedence over operations for congenital and valvular disorders, but whereas these have rapidly established themselves as standard procedures, **Wood**[1] feels—more than twenty years after the pioneer work of **Beck**[2] in America and **O'Shaughnessy**[3] in this country—that "operations [for ischæmic heart-disease] have not yet graduated from the experimental class." Recent reports from **Beck** and his fellow-workers[4,5] suggest however, that the mass of ingenious experiments in the intervening years is now beginning to bear fruit. Ischæmic heart-disease includes many clinical states—ranging from mild infrequent anginal attacks to massive infarction—which differ in their pathology, symptoms, signs and prognosis but which have an inadequate coronary circulation as a common feature and of this atheroma of the coronary arteries is by far the commonest cause. Symptomatically both medicine and surgery can offer a fair measure of relief to most patients but the surgical method, consisting in sympathetic denervation is not usually the symptomatic treatment of choice owing to the operative mortality and the occasionally unpleasant side effects. (The theoretical objection that it deprives patients of a useful warning signal has not been proved valid in practice even when pain is abolished a curious though not unpleasant, sensation of impending ischæmia remains.[6,7]) At the other extreme both medicine and surgery are still powerless to prevent or deal with coronary atheroma the primary cause of the disease. Between the highest and the lowest aim—curative and symptomatic treatment—**Beck's** operation has been designed to enable the heart to work adequately with an inadequate blood supply.

As has happened time and again with the elaboration of new operations **Beck's** work has thrown fresh light on old-established theoretical concepts. **Beck** clearly distinguishes two types of death from coronary-artery disease—one , due to electric currents in the heart which destroy the coördinated mechanism [of the cardiac cycle] the other due to muscle failure and destruction.[4] Currents which kill by initiating ventricular fibrillation—with or without actual muscle-destruction—arise in the electrically unstable heart , and electrical instability of the myocardium results not from an absolute shortage but from an uneven distribution of oxygen. Even the deeply cyanosed heart may remain electrically stable so long as it is uniformly cyanosed but electrical stability is destroyed by the 'oxygen differential' at the point of contact between cyanosed and oxygenated myocardium. Whether electrical instability leads to ventricular fibrillation depends on the strength of the current which the oxygen differential generates and on the threshold of fibrillation —a term by which **Beck** refers to the heart's disposition to fibrillate under prevailing working conditions. **Beck** believes that this dual concept of death from coronary-artery disease strikes at the very foundation of the coronary problem'. There is in his view no obligate relationship between abnormal currents and destruction of heart-muscle and he supports this view by the absence of infarcts old or recent, in a third of all victims of coronary-artery disease, and by the fact that extensive destruction of heart muscle resulting in failure occurs without producing currents strong enough to fibrillate the heart'.[4] The practical implication of this distinction is that one potentially lethal effect of coronary insufficiency is far more amenable to prophylactic surgery than the other. "There are two ways in which the crippled coronary circulation can be helped. One is by an even distribution of the blood that enters these arteries the other is by the addition of blood to that which enters the diseased arteries." Very little can be done at present to increase the amount of blood entering the coronary circulation coring out atheromatous plaques and other forms of direct arterial surgery are still beset with unsolved technical difficulties. Experimental attempts to anastomose systemic arteries, such as the internal mammary, with coronary arteries have not yet met with success and operations to convert the coronary sinus into an outlet for arterial blood even when dramatically successful at first do not maintain a reversed flow for more than a few months. To ensure a more even distribution of arterial blood is far simpler and this alone may suffice to abolish potentially lethal oxygen differentials.

Beck's operation consists essentially of four steps. First the coronary sinus is constricted to a diameter of about 3 mm by a ligature passed around it 2–3 cm from its opening into the right auricle. **Beck** claims that this allows a somewhat greater extraction of oxygen from the venous blood that—by causing mild venous stasis—it diminishes oxygen differentials in the presence of arterial occlusion and that it also produces inter-coronary channels. On the other hand this manœuvre is bound to increase capillary pressure and theoretically at least this may reduce the total inflow of blood into the coronary arteries. (If approach to the sinus proves technically difficult **Beck** advises that it should be omitted.) The second step is abrasion of the lining of the parietal pericardium and of the epicardial surface of the heart in order to bring about an inflammatory reaction which will induce the formation of new inter-coronary channels. Thirdly coarsely ground asbestos is applied to the denuded surface, and, finally, mediastinal fat is brought into contact with this area so that it can act as a graft None of these measures is new, but each step in the carefully planned sequence is said to contribute to the final result

Whatever criticisms may be levelled against this operation—several modifications have already been proposed[8–10]—it has the merit on first principles of seeking to imitate and supplement rather than to distort a natural process Post-mortem findings in men confirm experimental findings in dogs that an intercoronary circulation is established across the anatomical watersheds with progressive occlusion of any of the major coronary arteries[11 12], and this seems to be the heart's natural defence against threatening anoxia Furthermore, it seems that about 9% of people have congenital inter-coronary communications[12], and patients who make spectacular recoveries from major coronary occlusions may well belong to this fortunate minority The justification of **Beck**'s operation rests on experimental and post mortem evidence that occlusive coronary disease cannot promote an effective intercoronary circulation until it is severe, and on clinical evidence of dangerous oxygen differentials even with mild or moderate stenosis "The purpose of the operation is to place more people into the favourable [9%] group" who have an abundant inter-coronary network of arteries Negative merits of the procedure are its remarkably low immediate mortality (no death in the last 100 consecutive cases in the series of **Beck** and **Brofman**[4]) and technical simplicity, which eliminates from the operation the dangerous element of haste In the absence of congestive heart-failure, gross cardiac enlargement, and progressive symptoms (and not less than six months after an infarct) **Beck** advocates it for all cases of angina pectoris and of coronary insufficiency, and even for selected symptomless patients with a strong family history of early death from coronary disease It must be admitted, on the other hand, that—though **Brofman**[5] contrasts the "expected" mortality of 30%[7] with the postoperative mortality of 18% in 137 consecutive patients[5]—a follow-up period of from six months to five years cannot be regarded as adequate for so unpredictable a disease There is no accurate way of measuring either the degree of coronary insufficiency or the number of natural inter-coronary channels in any individual patient, and a carefully controlled trial, over at least ten years, of large, comparative groups will be necessary before the value of the operation in prolonging life can be assessed In their evaluation of symptomatic relief **Beck** and **Brofman** have been gratified by the results, but there are notorious pitfalls when patients "act as their own controls,"[5] especially when they have a disease where a strong psychologial element is increasingly difficult to exclude Nevertheless there is a good case for giving the operation an extensive trial, and results so far offer grounds for sober optimism

Young People Starting Work

The Certifying Factory Surgeon, as he was then called, was one of the earliest instruments created by the State in its attempt to safeguard the health of young people Originally, his primary function was to act as a check on their employment in contravention of age limits imposed by statute, and his critics said that he was sometimes too willing to believe that stunted youngsters were of the prescribed age The Factory Act of 1874 made it necessary for a child to have a surgeon's certificate that he was 13 before he entered on full-time work free from schooling, but the Act was often evaded **Housden**[1] tells how a Birmingham brass-founder, seeing a lad who looked very young, asked his age The boy replied that he was 13, he knew he was 13 because his mother told him so But when asked how old he was before his mother told him he was 13, he replied "9", and further investigation showed that, though duly certified, he was only 9 years old Another side of the certifying surgeon's job—one that assumed added importance with the years—was to satisfy himself that the children passing before him were physically fit for the work they were required to perform, but disability was prevalent and standards low, and it may have been that here again the surgeon felt that he could not afford to be too critical "Passing before" is perhaps the correct expression remuneration was small and facilities for any examination were sometimes absent Under the prevailing conditions it was hard to do good work Now circumstances have greatly changed, though there are still some difficulties The newer outlook is intended to be much more positive It is the declared intention of the State that the work of supervising young entrants to industry should dovetail with that of the School Medical Service, the records of which are available to the Appointed Factory Doctor on request In practice, these records are not very often sought, and when sought they cannot always be produced by return of post, and there are inevitably cases in which the recorded findings of the school health service do not altogether coincide with those of the factory doctor

Herford,[2] as an appointed factory doctor, presents a study of adolescents at work in the Slough area (predominantly light industry) His experience leads him to conclude that the work of the appointed factory doctor, suitably reoriented to make full use of his unique opportunities, could contribute far more to constructive medicine than it has done hitherto He points out that the Ince Committee, which considered in detail most of the agencies concerned with the welfare of youth in industry, made no mention of the work of the appointed factory doctor, and that the Youth Employment Service, set up in 1948 as a result of the Ince report, has had little contact with him From this, **Herford** goes on to make recommendations for the improvement of the appointed factory doctor's work and the increase of his contribution to the welfare of young people He comes to the conclusion that the appointment of such doctors should be essentially whole

time, that they should belong primarily to the staff of H M Medical Inspectorate of Factories, though they should also hold an appointment with the local authority as an assistant school medical officer, that all young persons should be examined regardless of occupation, that the appointed factory doctor should be medical adviser to the Youth Employment Service and should be provided with a secretary seconded from the staff of that service, that school medical records should be submitted automatically to the appointed factory doctor when the children leave school, and that it would be an advantage to have the appointed factory doctor associated with a university department

There will be general agreement about the need for skilled vocational guidance for young people entering industry (especially for those at either end of the scale of physical and mental fitness), for even in these days the choice of a career is left to blind chance—very much a matter of trial and error The best use is by no means always made of our really able young people, and many of the handicapped could be helped to better things [3] As to how improvement can be made, the issues are neither entirely industrial nor entirely medical, decisions turn largely on the background and inclination of the youth and often on the attitude of the parents It would, we believe, be right for the family doctor to take a more active part in vocational guidance, especially of the handicapped child if he would familiarise himself with the nature and demands of the industry of his area none could do it better, and it is fascinating and rewarding work This would not remove the need for a person specially appointed to do the kind of work done by the appointed factory doctor (who has, of course, other statutory duties), but in general we are not persuaded that the multiplication of official doctors would be a good thing, or even economically sound In practice, HERFORD's proposals would probably imply organisation on a geographical basis corresponding to that of the major health authorities, and whether that offers the best prospect of an improvement is open to doubt The questions he has raised call for careful study How best to further the well-being of young people starting work is not just a problem of industrial health, is not this important task one that should fall within the ambit of the general health service itself?

Annotations

THE PREGNANCY AND THE CHILD

MEDICINE is frequently enriched by contributions from other disciplines, and Dr Stott's article from an institute of education, which we publish this week, could prove to be the starting-point of a new approach to some of the processes concerned in mental retardation In a carefully controlled study of 102 mentally retarded children he has found an association between retardation, congenital malformation, and frequent ill health in early life, and he has connected this syndrome with physical and emotional disorders in the mother during pregnancy He therefore suggests that stress in pregnancy may determine biological inferiority in the child, either directly or by facilitating a latent genetic influence But in considering the evidence for this hypothesis it should be noted that the survey was retrospective and that the analysed data are based on the mothers' recollection supported by medical records and health visitors' cards No genetic histories were obtained, and, apart from the knowledge that the retarded children were of normal appearance, we have no details of their clinical classification

Little is yet known about the genesis either of undifferentiated mental retardation or of congenital malformations in man Certainly, normal development can be altered by prenatal environmental influences, but in the case of congenital malformations there is general agreement that the noxious influences must be in operation at the time of organ differentiation, which in the human fœtus is completed by the 12th week of intra-uterine life Anomalies arising after this must be traumatic or regressive changes due to mechanical or chemical agents, and for an illustration of the fact that grave damage to the mother does not necessarily affect the infant in utero one need look no further than the remarkable case recorded by Mr Rowbotham and his associates on p 1016

Experiments on animals have confirmed this time specificity of environmental influences and have also indicated the wide variety of physical and chemical disturbances which may produce congenital malformations The present position has been summarised by Gluecksohn Waelsch [1]

> ' . . . thus we have reached . . . the central problem facing all 'teratologists,' namely that of the mechanisms by which causal agents produce malformations It is of utmost importance to realize that the nature of these mechanisms is independent of the nature of the causal agent In this respect genetically caused abnormalities do not differ in any way from those produced by deleterious agents, e g, X rays hormones, anti metabolites, nutritional deficiencies or others The pathways by which they achieve their end effects may be the same or different but they are independent of whether the original deviation from normal was caused by a gene or some other factor '

Though it is evident that in animals many different maternal conditions may produce a common final syndrome in the embryo, experience with man is by no means so clear The syndromes associated with maternal rubella and irradiation appear not only time-specific but also to some extent type specific Rubella is associated with deafness, cataract, and congenital heart disease, while irradiation is associated with microcephaly Apart from these two conditions, no other environmental factors have been proved consistently to cause congenital defects in the human fœtus Among several surveys, those of Carter [2] and Creamer [3] are specially valuable here Carter investigated many maternal illnesses during pregnancy with negative results, and Creamer in a controlled follow up study of the children of mothers with pregnancy toxæmia found no preponderance of either congenital malformations or early ill health The known associations of congenital malformations with multiple pregnancy, prematurity, multiparity, pregnancy in very young or elderly mothers, and male infants [4] [5] are probably not environmentally determined

Even less clear are the facts in regard to mental retardation A high proportion of mental defectives may have congenital malformations of the brain,[6] but these are not necessarily due to noxious environment Moreover mental defect is sometimes undoubtedly caused by perinatal damage to the brain.[7] Without genetic data and birth histories in Dr Stott's cases it is hard to say whether an alternative explanation to that advanced by him might be more reasonable in terms of current knowledge.

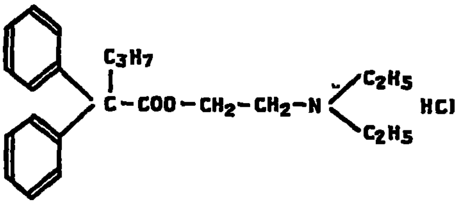
Since existing explanations account for only a small proportion of mentally retarded children, it is impossible to ignore Dr Stott's hypothesis of what might be termed intra-uterine protophrenia, and to test this hypothesis in a prospective manner an investigation on a large scale should be undertaken as a multi-disciplinary project. Meanwhile, however, there is no need to add to the anxieties of the pregnant woman by making premature suggestions that she can worry herself into bearing an abnormal child.

BIOTRANSFORMATION BLOCKADE

A FEW years ago much interest was aroused by reports of the remarkable properties of a compound related to a spasmolytic 'Trasentin'. Given the code name of SKF 525 A, this compound is β-diethylaminoethyldiphenylpropylacetate hydrochloride.



Trasentin differs in having no propyl radical.

The striking feature of the action of SKF 525 A is that, in doses at which it has no obvious effects itself, it greatly prolongs the action of various drugs on the central nervous system. Thus pre-treatment with SKF 525 A increases the duration of hypnosis after administration of hexobarbitone in mice by 15 times and in rats by 37 times. In rats, doses of hexobarbitone which alone were ineffective produced sleep for an average of 35.2 minutes when SKF 525-A 25 mg per kg had previously been given by mouth.[8] Amounts as small as 1 mg per kg significantly prolonged hexobarbitone hypnosis in mice, but even at 50 mg per kg, SKF 525 A did not notably alter the toxicity of hexobarbitone in rats. The effect is not evident with all barbiturates, thus the action of pentobarbitone is prolonged but not that of its thio analogue, thiopentone. The action of diethyl ether or nitrous oxide is not prolonged, whereas that of some other central-nervous-system depressants (including chloral hydrate, morphine, codeine, pethidine, amidopyrine, and phenytoin) is prolonged, as are the stimulant actions of amphetamine sulphate and of strychnine. Such effects might be produced by one or more of several possible mechanisms[9], but there is clear evidence that SKF 525 A interferes with the rate of metabolism or biotransformation of the drug concerned.[9 10] It inhibits the enzyme systems which oxidise the side chains of hexobarbitone and pentobarbitone, deaminate amphetamine, convert codeine to morphine by ether cleavage, conjugate morphine, and dealkylate pethidine, amidopyrine, and ephedrine. It was found that these enzyme-systems were located in the microsomal fractions of liver homogenates, but also required reduced triphosphopyridine nucleotide (TPNH) and oxygen. These seemed to be supplied in the supernatant of centrifuged liver homogenate. A requirement for TPNH rather than TPN indicates an unusual oxidative pathway, and the normal cytochrome system does not seem to be involved. That a peroxide-like intermediate takes part is suggested by the work of Brodie et al.[11] The possibility that SKF 525-A acts by blocking the oxidation of TPNH is not borne out by experiment.[10] Furthermore, it does not inhibit certain enzyme-systems which require TPNH and oxygen, or which require TPNH but proceed anaerobically. It does interfere with conjugation of morphine and hydrolysis of procaine by enzyme systems which do not require TPNH. Iproniazid, the isopropyl derivative of isoniazid, has been shown to block the same drug enzyme systems as does SKF 525-A.[12]

There is no clear therapeutic use for SKF 525 A, but it opens up an important field for the further study of drug metabolism.[13] Brodie[11] has put forward the idea that the "microsomal enzyme systems of liver may be there to 'detoxicate' foreign compounds". Substrates normally present perhaps have specific mechanisms for their metabolism, the foreign compounds being dealt with by rather non-specific microsomal systems. It seems that the microsomal drug enzyme systems may be absent in lower animals, and this may explain species differences in tolerance to certain drugs—exemplified in frogs, which excrete hexobarbitone unchanged.

THE AFFAIR AT BATH

BATH was used as a healing centre by the Romans. The Bath General Hospital, built with money raised by Beau Nash and opened in 1742, has latterly been an important centre for the treatment of rheumatism, and in 1934 it changed its name to the Royal National Hospital for Rheumatic Diseases. Even then it badly needed rebuilding, and funds were raised for the purpose, but the war prevented their use, and in 1942 part of the hospital was destroyed by a bomb. When the National Health Service began, the money (£130,000, of which £89,000 had been specifically subscribed for the new building) was taken away for the common pool. As it was supposed that plans for a new building would nevertheless be fulfilled, the hospital was neither repaired nor modernised.

Its present condition is deplorable. The research laboratory is partly in the mortuary and the "plaster room" is a corridor. There is no operating theatre at all, the wards are ill arranged, the lifts are inefficient, and the X ray department was condemned ten years ago. Yet, because of the spirit of the staff, and the quality of their work, patients are admitted to the 130 beds from all over the country, and even from abroad. The demand on it proves that, even though many large general hospitals have their own rheumatism units, a valuable purpose is served by having *at least* one such special hospital, of national standing, where rheumatism is intensively studied and standards can be set. Despite all difficulties, Bath has so far managed to maintain a notable team in which the patient gets expert care from physician, orthopædic surgeon, radiologist, physiotherapist, occupational therapist, and social worker—all especially interested in his condition.

That such a hospital should become a casualty of reorganisation shows that the reorganisation is faulty. With so much else to do, the regional board puts regional needs first and finds itself unable to give more than third priority to a rebuilding project which it regards as a national as much as a local responsibility. The Ministry of Health, on the other hand, takes the view that money for capital expenditure on hospitals should be distributed through the regional boards. Both arguments sound reasonable enough in themselves, but neither justifies the progressive administrative destruction of a valuable institution. Under the National Health Service no effort has been made to fulfil the particular object for which the hospital raised what was then a large sum of money To many people that object still seems important, and if they are wrong, they are entitled at least to a full explanation of why the Bath Hospital can properly be allowed to disintegrate Otherwise, if the Ministry seriously wants the public to retain their interest in hospitals, and resume their former habit of benefaction, it will have to reconsider its decisions

THE BOMB TESTS

As Lord Cherwell was at pains to emphasise in the House of Lords (in the speech reported on p 1046), no-one who is not in possession of secret details about the British nuclear weapons can really say what the result of the forthcoming tests will be But these details may not be so important, for what is far from secret and matters much more is the mounting quantity of radioactive substances that are being released in test explosions and which can be measured as they fall out by anyone who cares to take the trouble If the plan for Christmas Island is to fire fusion bombs with no great quantity of fissionable material added, then the amount of radioactive substances released will be small, and on the existing evidence the hazard to health will be negligible Even if some of the so called "dirty" bombs are exploded, the disastrous consequences prophesied by some people are still improbable Nevertheless, we persist in our view that the continuation of test explosions increases the chances of doing serious harm to a sizeable number of people and that negotiations for the abolition of such tests should be undertaken with a far greater sense of urgency than the Government have hitherto shown We are alarmed at what may happen if tests go on much longer and we are unconvinced that harm has not already been done It seems that the Government, in their attitude to the control of nuclear tests, are depending too much on certain reassuring facts and not making enough allowance for the big gaps in knowledge

The extent of what is known about radioactive fallout was examined by Dr Willard F. Libby, commissioner of the United States Atomic Energy Commission, in an able address to the American Physical Society on April 26, and we reported some of his remarks last week [1] By the data at his command, he is convinced that the risk to the health of the world's population from nuclear testing at the present rate is small As Dr Libby pointed out, there is good reason to believe that most of the spontaneous mutations of the human species are not due to radiation but to other causes For this and other reasons, therefore, the genetic effects of irradiation of the gonads by radioactive fallout from tests so far carried out is likely to be very small The Medical Research Council committee [2] put the population dose to the gonads from fallout at less than 1% of the natural background radiation (The alarming figure they gave for the addition made by diagnostic radiology was at least 22%) But, though the gonad dose from fallout is at present small, therefore compared with some other sources, there is no escaping the fact that any additional exposure, from whatever source, must be expected to raise the mutation rate and the effect of radiation to which the whole population is exposed, such as that from fallout, is likely to be a particularly telling addition The genetic risk of past and future nuclear explosions has certainly been exaggerated in some quarters, but it seems far wiser to exaggerate than underestimate, as Lord Cherwell does when he says that "even the most cautious experts agree that the effect of adding an extra 100% or 200% to the natural background dose would be negligible The M R C committee, on whose findings Lord Cherwell puts we think, too optimistic an interpretation said

> "… we feel bound to state our opinion that it is unlikely that any authoritative recommendation will name a figure for permissible radiation dose to the whole population, additional to that received from the natural background, which is more than twice that of the general value for natural background radiation The recommended value may, indeed, be appreciably lower than this"

In coming to the conclusion that strontium 90 in bone had not reached, and was unlikely soon to reach, anything like a dangerous level, Dr Libby based much of his argument on a comparison between cosmic rays and the radiation from strontium 90, which has a radioactive daughter, yttrium 90, emitting energetic β rays The ionisation density along the track of these rays is very similar to that generated by the mu-mesons of cosmic rays and their disintegration electrons But, though it is widely believed that radiations of the same ionisation density have very similar biological effects for the same energy absorbed, it is not yet certain that the effects of an external radiation like cosmic rays are a valid standard for assessing what a radioactive substance fixed in the body can do Moreover a comparison between leukæmia and bone-cancer statistics in people exposed to different doses of cosmic radiation, because of the altitudes at which they live, may not be as reassuring as Dr Libby believes Only vital statistics for large populations living at high altitudes would be fully convincing on this point To argue from the effects of cosmic rays that it is safe to go on releasing strontium 90 may be fallacious it would perhaps be wiser to rely on a study of the action of strontium 90 in animals, and here the findings so far reported are much less comforting in their implications for man

Disquiet about strontium 90 in bone springs largely from the uncertainty about the existence of a threshold concentration below which there is no risk of leukæmia or tumour formation In an appendix to the M R C report, Mayneord and Mitchell referred to the lack of information about the action of very small doses and to the animal experiments that had led some investigators to postulate a threshold level They added

> "It appears however that each unit quantity of radiostrontium absorbed by the bone confers a certain probability of bone tumour formation, the tumour development time perhaps decreasing and the tumour incidence increasing with the dose On the whole, the experiments seem in favour of a proportionality between the frequency of tumours produced in a given length of time and the amount of radioactive material in the body even at low dose levels"

If there is no threshold, the body burden of 1 microcurie laid down by the International Commission on Radiological Protection as "permissible" for those exposed to strontium 90 in their work may be too high, and the burden of 0 1 microcurie now held to be acceptable for the general population, with its proportion of young children, may be similarly misleading

On the assumption that a proportional relationship between strontium-90 content of bone and tumour formation applies to very small doses, the Atomic Scientists' Association estimated that a hydrogen bomb of Bikini type, exploded high up, may eventually produce bone cancers in 1000 people for every million tons of T N T of equivalent explosive power The cautious statement [3] of the association's committee emphasised that the no threshold hypothesis was the most pessimistic view, but if it is correct the committee's figures may be an underestimate, since they did not allow for the radiation dose in children before or after birth To dismiss as brusquely as Lord Cherwell does the views of Professor Rotblat's committee is to accept a grim responsibility

A linear relationship between exposure to radiation and subsequent damage was suggested by a study of leukæmia in patients with ankylosing spondylitis treated by irradiation Some other relationship may ultimately prove to be the correct one; but in another appendix to the M.R.C. report Court Brown and Doll said that there was no evidence of a threshold below which no increase in leukæmia was produced. On the other hand, as Loutit[4] has observed, there are reasons why leukæmia should not be taken as a model for all radiation-induced malignancies, and what little quantitative evidence there is of the carcinogenic properties of radiostrontium suggests that the relationship is not linear and that there is some form of threshold or effective latent period. Much is still dangerously uncertain, and the correct conclusion, as Loutit puts it, "in the present state of scientific knowledge is that a linear relationship sets the limit and indicates the worst possible conditions, so that it would be prudent to go easy until the real facts are ascertained." It is against the Government's apparent reluctance to do all they can to "go easy" by pressing for an early agreement on the limitation or abolition of nuclear explosions that we protest.

LONDON TROPICAL MEDICINE

IN medicine, 1899 was a very long time ago; and in his fascinating account of the first fifty years of the School of Tropical Medicine in London Sir Philip Manson-Bahr[5] shows incidentally how much the world has been changed by that originally modest enterprise.

At the end of the 19th century, Britain had a vast tropical empire, in many parts of which the death-rates were appallingly high. The doctors sent to the Colonies were often ill equipped even to use what knowledge our profession then possessed of tropical diseases; and Patrick Manson, returning to England after twenty-three years in the East, saw that his most important task was to promote a school for teaching and research. Appointed medical officer to the Colonial Office in 1897, he enlisted the support of Joseph Chamberlain (his Secretary of State), as well as of the General Medical Council; and two years later the London School of Tropical Medicine, associated with the Albert Dock Hospital, was opened with 28 students. (The Liverpool school had begun work six months before.)

At first most of the students were sent by the Colonial Office, but many came from missionary societies, the Forces, and other organisations, and in 1912 the school was much enlarged. The Dockland site had advantages in that the students were secluded from the London whirl, but after the first world war a move was made to central London, where a hotel in Endsleigh Gardens became the combined school and hospital under one roof. Then in 1925 the school was merged in the London School of Hygiene and Tropical Medicine, and in 1929 the fine new buildings in Gower Street were opened. Two years later it became part of the University of London, and soon afterwards it incorporated the Ross Institute and took over the malaria laboratory at Horton Hospital, Epsom. The Hospital for Tropical Diseases remained at Endsleigh Gardens until it was closed at the outbreak of the second world war, after which teaching continued in the Dreadnought and other hospitals, and from 1944 in a former nursing home in Devonshire Street. With the passing of the National Health Service Act the decision was taken not to build the new hospital for which many of us hoped; and instead a section of St. Pancras Hospital became in 1949 the clinical centre of the school, under the board of governors of University College Hospital. With the end of the fifty years this book closes.

Sir Philip was for a decade director of the clinical division of the school; and his very large acquaintance will find in his history the qualities they could expect—the knowledge, the zest, the humour, and the humanity that bring such stories to life—not to mention the miscellaneous pictures. The official facts are all there; but so are the people who made the facts and whom they merely reflect. Perhaps nobody but this author could (or would) have attempted to provide biographies of a hundred of these people—doctors, scientists, and technicians—some of them long since part of medical history but others still working at the school. Even the reader who looks at nothing but these biographies will get some idea of the achievement of London tropical medicine through its exciting expeditions and its exciting discoveries, still happily continuing.

Sir Philip likens the school to an insect which has passed through the egg, larval, and pupal stages, to blossom forth as a full fledged imago. But it performed great feats even in the earthbound or submarine stages of this analogy, and who can say where it may soar on wings?

RADIOGRAPHERS IN THE N.H.S.

USEFUL though arbitration can be in settling a disputed issue, the arbitrator does not necessarily take a long view; and in the National Health Service the use of arbitration does not in any way absolve the Ministry of Health of its responsibility for seeing that the service is properly maintained. If the Ministry is inclined to think that further attention to the shortage of radiographers is unnecessary because they had an award last November from the Industrial Court, we hope it will look again at the facts of a disturbing situation.

We need not recapitulate the criticisms of the award which have been made at length in our correspondence columns. Nor need we reproduce all the arguments lately set out in the Society of Radiographers' dignified statement to the press.[1] For the moment we are concerned chiefly with the evidence that despite, or because of, the award the radiographic services of the N.H.S. are deteriorating and will continue to do so. A reduction in the number of radiographers and the amount of work they do might be intelligible as part of a deliberate policy, fully discussed with the Central Health Services Council before it was adopted; but it is wholly unacceptable if it arises merely from the Government's antiquated conviction that in public services people need not be paid the kind of salaries they could earn outside.

The Society of Radiographers says[1] that whereas the Ministry last November estimated the general shortage at about 20% *it is now nearer 25%*. Some local shortages are so acute that departments have already restricted their services—the latest example being a warning that "the X-ray departments in the Lewisham Hospital Group will soon be manned by a 'skeleton staff.'"[2] In some places departments have been kept open only by radiographers working at a pressure which neither can nor should be continued for long periods. That in time of difficulty virtue should be its own reward is in keeping with the medical tradition; but, when one expects people to be ready to make whatever personal sacrifices are required to keep an institution running, one cannot also expect them to accept, permanently, a lower rate of pay than their skill and quality should command. The Society of Radiographers, pointing out that its own problems are closely related to similar ones in other parts of the N.H.S., puts its case fairly and with restraint:

> "The National Health Service is a social experiment of wide scope: those who are involved in it expected stresses and strains during its formative years and were prepared to make sacrifices to overcome them. But the society is sure that the general public, who use the service, would not wish these conditions to be regarded as other than temporary maladjustments and that they would not wish them to persist at the risk of a serious handicap on the service as a whole."

Special Articles

THE MAGNITUDE AND COST OF MENTAL ILLNESS IN THE COMMUNITY*

Sir Frederick Armer
KBE, CB, MC
CHAIRMAN, BOARD OF CONTROL, MINISTRY OF HEALTH

The public are beginning to take an interest in the mental health problem, but they do not realise what a transformation has taken place in mental hospitals during recent years. People are beginning to lose their fear of the mental hospital, and voluntary patients are flocking to the hospitals. I have been in the Ministry of Health for thirty seven years and I have visited a good many hospitals. A visit to a mental hospital in the 1920s was a depressing experience. Most of the hospitals were drab in the extreme and the patients were sullen and often violent, regarding the nurses as gaolers. They had the atmosphere of the old poor law institutions which, indeed, in many respects they were. But if you go into our *mental hospitals today you will find*, with some exceptions, that the places have been brightened up with light paint and a good deal of imagination, and that good relations exist between patients and staff. Before the war it was common in the wards of mental hospitals for visitors to have things thrown at them; patients are now more amenable, because of a better understanding of their needs, the expansion of the open door principle, and, not least, the use of drugs which research has placed at the disposal of the hospitals. Brighter as the picture is, the hospitals are working under heavy pressure and overcrowding.

VOLUNTARY AND CERTIFIED

In speaking of the growing use of our mental hospitals by voluntary patients we are apt to talk of percentages. We say that about 75% of the patients now entering the hospitals do so voluntarily. This is true, but it does not convey to the ordinary man what is really happening. In fact, it might lead him to think that of every four patients entering mental hospitals three who otherwise would have been certified now go in as volunteers. This is not the picture at all. The number of patients entering our hospitals as certified patients is not decreasing; in fact, it has risen during the past few years and now stands at between 18 000 and 19,000 a year. It is the number of voluntary patients that is going up by leaps and bounds; it has more than doubled in the past ten years, from 27,000 in 1947 to 60 000 last year. I think there are three reasons why this large increase in the number of voluntary patients has not yet been reflected in a reduction in the number of certified patients. One reason is the increase in the number of certified old people—it is not always possible to secure treatment for them without certification. The second is that many of the voluntary patients are receiving treatment at an early stage and would not have become sufficiently ill to be certifiable for a number of years. But the main reason is that large numbers of the voluntary patients although mentally ill and needing treatment would never have become sufficiently ill to be certifiable. This means that our mental hospitals are making an impact on that vast amount of non-certifiable mental illness that [illegible] exists in the community.

With all this quick turnover of voluntary patients there remains the hard core of the more [illegible] patients. Their number has remained [illegible] constant [illegible] the years at about [illegible]. [illegible] in spite of advances [illegible] mental hospitals [illegible] more than a year and nearly 50% more than ten years. In other words 60,000 patients have been in mental hospitals for more than ten years.

Their only hope is in research. For example, schizophrenia is a mystery but it fills a third of the 150,000 occupied mental hospital beds in this country.

THE COST

You may ask why should laymen be interested in what might be regarded as a medical problem? Apart from the humanitarian aspect, there is a serious economic aspect which must be of concern to us all. Mental illness and mental deficiency cases occupy nearly half the hospital beds in this country, and the cost for treatment, ascertainment, care, and aftercare is about £60–70 million per year chargeable to public funds. And we know that in the community at large between a quarter and a third of all absence from work due to sickness is on account of mental and neurotic illness. That does not tell us much until we begin to look at the figures. It means that 80 million days of work are lost every year through mental and neurotic illness involving a loss of some £120 million per year in wages and, of course, a large loss of production. In addition, about £20 million a year is paid out of sickness benefit funds to these sufferers. This is a very serious economic problem and we are bound to ask ourselves: "Is it inevitable that there should be all this mental illness in the community at large? What are the means of preventing it? Is it inevitable that 60,000 patients should have to spend more than ten years in mental hospitals, and is it inevitable that mental illness is a concomitant of old age?" *Research* is the only answer to these questions.

VOLUNTARY EFFORT

You may ask—people do ask—why is it necessary for a voluntary fund to be raised for this research; why does not the Government provide the money and carry it out? The Medical Research Council do in fact spend a considerable amount on research into mental illness and mental deficiency, but it is difficult for the Government to provide out of taxes enough money to meet all the many demands on them, and voluntary funds are an invaluable help.

It is more than a question of money. A voluntary body with funds at its disposal can do things which a Government department cannot do. It can inspire enthusiasm and create a crusading spirit which no Government department is equipped to do. And in this field a crusading spirit is very necessary.

---

* From an address [illegible] general meeting of the Mental Health Research Fund on [illegible] 1957.

WORLD HEALTH ORGANISATION

The tenth World Health Assembly was opened in Geneva on May 7 by Prof. J. Parisot, the outgoing president, who declared that more importance [illegible] given to industrial development than to systematic research into measures to ensure the safety of the worker." He emphasised the special possible dangers of trials of atomic weapons. Dr. S. H. Al Wahbi (Iraq) was elected president, and in his address he welcomed the delegates from Ghana and from four countries which have resumed active membership.

Dr. M. G. Candau, the Director-General, claimed that eradication was the only possible solution of the malaria problem, and it was the most economical one. Dr. John E. Fogarty, a member of the United States Congress, said that his government had invited the World Health Assembly to meet next year in the United States. [illegible] Mudaliar (India) proposed that the Assembly should appeal to all governments to stop atomic bomb tests. He was supported by [illegible] [illegible] the People's Republic of [illegible] member of W.H.O. [illegible]

[illegible]

Before Our Time

THE CRISIS OF 1911-13

Lloyd George and the Doctors

SIR JOHN CONYBEARE

K B E, M C, M A, D M Oxfd, F R C P

THE present dispute with the Government makes it interesting and perhaps not unprofitable to recall what was perhaps the biggest and the most critical fight which has ever taken place between a Government and the medical profession This followed the introduction of the National Insurance Bill by Mr Lloyd George on May 4, 1911, and lasted with increasing bitterness until the British Medical Association withdrew its opposition

It must be borne in mind that the B M A 's opposition to the National Insurance Bill was not over remuneration alone It also involved such questions as payment by capitation fee, freedom of choice of doctor, contract practice, and control of the medical service by laymen A brief digression on the conditions of medical practice in the earlier years of the 19th century may help to explain the background of the struggle

Conditions of Medical Practice

In 1912 the total number of practitioners on the Medical Register was 41,053 Of these approximately 9000 were abroad or in the Services Of the other 32,000, probably well over 20,000 were in general practice, working single handed or in partnership The remaining 12,000 doctors included consultants and specialists (far fewer than they are today), those holding junior appointments in hospitals (voluntary or municipal), those engaged in public health or teaching posts, and the retired In addition, however, to the above, there were many who spent long years as assistants to the owners of general practices, particularly those in industrial areas Not infrequently the assistant resided above the surgery, sometimes in rather poor quarters, doing the night work, while his principal had his home in a residential district, often some miles from the practice Salaries of assistants were low Practices were bought and sold, and in normal circumstances, especially in industrial areas, the purchaser could be reasonably sure of retaining most of the patients Payments received from the sale of practices were of course regarded by the Inland Revenue as capital and not income—an important feature after 1914 when income tax had become burdensome

Before the National Insurance Act many practitioners in industrial areas held appointments with friendly societies and undertook the medical care of members on a capitation-fee basis This usually included both medical attention and drugs The annual capitation fee, according to a statement by the medical secretary of the B M A, was sometimes as low as 2*s* 6*d*, though the average was about 4*s* It was estimated that contract practice in all its forms provided for more than half the working population of the country Although currency has depreciated since 1914, there can be little doubt that doctors in working-class areas were grossly underpaid, and that the conditions under which they had to work resulted in what on the whole was inadequate service to the patient Moreover the friendly societies exercised considerably too much control over the doctors whom they paid so poorly It is not surprising, therefore, that when the National Insurance Bill appeared on the horizon it met a hot reception from the medical fraternity, so many of whom had for years had every reason for dissatisfaction at the prospect of a big increase in contract practice

Medical Aspects of the Bill

The National Insurance Bill introduced compulsory insurance under a contributory scheme for all manual workers and all other employed persons with incomes below £160 a year The benefits included, insurance against sickness and unemployment and the Bill also provided free medical attention The value of the Bill as a far-reaching measure of social reform was acknowledged on all sides, but from the beginning the B M A, which represented a majority of practitioners, criticised the terms, both financial and administrative, under which medical care of the insured was to be provided Nor did the B M A waste any time in formulating their demands On May 31, 1911, the main heads of policy were approved unanimously by a Special Representative Meeting These formed the basis of the "six cardinal points," which became the minimum demands of the B M A

In slightly condensed form, these were

1 Income limit of £2 a week for those entitled to medical benefit

2 Free choice of doctor

3 Medical benefits not to be administered by friendly societies

4 Method of remuneration to be according to the preference of the majority of doctors in each district

5 Amount of remuneration to be what the profession considers adequate

6 Demand for adequate medical representation on all committees

Mr Lloyd George attended a B M A Representative Meeting He spoke in a conciliatory vein and replied to many questions put to him by the chairman The point on which the Chancellor was most emphatic was that of the income limit of £2 a week This demand by the association would in his opinion be vetoed by all parties in the House of Commons As regards method of remuneration he felt that payments for individual attendances, however attractive in theory, would not be practicable In general he was in favour of free choice of doctor and thought that medical benefits should be administered by health committees and not by friendly societies

From a very early stage it was clear that, although the Bill would lead to a great increase in contract practice with capitation fees, the chief objections were financial The *British Medical Journal* of May 13, 1911 (only nine days after the introduction of the Bill) emphasises this

> "In considering the position with which the profession now finds itself confronted, it is, perhaps, unfortunate, but certainly inevitable, that the question of remuneration must bulk large"

Over and over again the limitation of medical benefits to those with incomes of £2 a week or below is stated as a sine qua non if the medical profession is to accept service under the Act Nor is there any concealment of the motives Practitioners felt that capitation fees for patients earning £2–3 a week would not compensate them for the loss of private fees from this group Living in 1957, it is only fair to bear in mind that a weekly wage of £2 in pre 1914 days was by no means rock bottom Indeed many earned far less Thus in the early years of the century agricultural labourers and many others were judged fortunate if they were paid even £1 a week

Meeting followed meeting, nor were they attended by general practitioners alone On June 1, 1911, a mass meeting of members of the profession was held at the Connaught Rooms in London On the platform were the presidents of the Royal Colleges (Sir Thomas Barlow and Mr H T Butlin) and other famous consultants including Sir Victor Horsley and Sir William Church Sir Thomas Barlow was out of touch with the spirit of the meeting but Mr Butlin was cheered to the echo when he recounted an experience of his own when he had operated on a Jewish woman in the East End of London

He told the meeting that, although the patient's husband and family belonged to a club paying one penny a week each for their doctoring, there had been no difficulty in paying his fee of 100 guineas for the operation, besides the nursing-home expenses Mr Butlin and his audience were well satisfied that no person with an income of over £100 a year should be allowed to participate in the medical benefits of the Bill

Other speakers were even more emphatic Dr Tonkin (Fulham) thought the income limit should be £70 and not £100, while vociferous cheering greeted a peroration by a Dr Townsend "if we have to go under, we would go under fighting and would not be starved out"

As enthusiasm waxed at successive B M A meetings, new demands were formulated in addition to the six cardinal points—special fees for night calls and emergencies, payment for illnesses caused by misconduct, anæsthetic fees, and mileage payments Wigan went the whole hog and adopted a resolution "that all clauses of the Bill which relate to medical attendance are bad, and should be deleted from the measure"

By July, 1911, the B M A had made good progress in circularising not only their own members but all doctors, enclosing a form of undertaking which the recipients were asked to sign and return In this somewhat verbose document they undertook not to give any service under the Bill except by permission of the B M A They were also asked to sign a Memorial to the Government and Parliament In the same circular the medical secretary of the B M A, Mr J Smith Whitaker, of whom more anon, appealed for donations to Defence Funds, both central and local Although the response to the Undertaking was good—ultimately 27,000 out of some 40,000 on the register—the Defence Fund was less satisfactory in spite of repeated demands throughout the campaign, only 13,000 subscribed The total subscribed or guaranteed was quite insufficient to be of any value for its purpose of financing doctors who lost money by their refusal to accept service under the Bill

The Insurance Bill and Voluntary Hospitals

By mid-1911 members of the B M A were beginning to turn their attention to voluntary hospitals and their staff The Ashton-under-Lyne division unanimously "Viewed with disfavour the apathy displayed by the medical faculties of many universities and teaching schools" Cardiff went one better and suggested that all the honorary staffs of hospitals insist on payment for treatment of insured persons A little later, a letter from Mr W F Brook, F R C S, in the *British Medical Journal* estimated that if all honorary staff insisted on payment they would receive some £16 million annually Mr Brook was confident that this sum would be forthwith donated to the B M A Defence Fund Mr Chas Wray, F R C S, was in favour of calling out all the honorary staff and students in the Kingdom unless the Government gave in

The voluntary hospitals were disturbed at the prospect of a loss of income from subscriptions by the public if the Bill became law, and there was some discussion regarding charges to insured persons, but no serious attempt seems to have been made to bring treatment in hospital into the medical benefits under the Bill

Trouble in the B M A

On Nov 30, 1911, Mr Asquith as Prime Minister invited the medical secretary of the B M A, Mr J Smith Whitaker, to become deputy chairman of the Insurance Commissioners Mr Smith Whitaker, whatever his private views may have been, had in his capacity as medical secretary been the chief executive organiser of the B M A.'s opposition to the Bill Before replying to the Prime Minister's invitation he placed the decision in the hands of the council of the B M A After a long discussion the council by 38 votes to 3 advised acceptance of the post on the ground that it would be of great advantage to the profession to have in the important position of vice chairman a medical man who understood, and was sympathetic to, the attitude and aims of the B M A

It did not take long for the storm to break Within a few days of the news of the appointment, meetings of B M A branches and divisions were passing resolutions condemning the action of the council Dr F J Smith, physician to the London Hospital, wrote to the *Times* a letter headed "The Great Betrayal," in which it was clear that open warfare was developing between the B M A and many of its members who were anxious for more drastic action The official policy of the B M A was not to refuse to work the Bill on *any* terms, as desired by the extremists, but to demand our *own* terms

At Manchester on Dec 14, 1911, the insurgents held a meeting to establish a National Medical Union, the object of which was organised refusal of service under the Bill The policy of the B M A was denounced as "negotiate and procrastinate" Wild scenes of disorder occurred and speakers, including Sir James Barr, who tried to defend the council's action, were howled down A similar meeting of rebels was held in Birmingham, but the largest and most highly emotional meeting was held at the Queen's Hall in London on Dec 19 The hall and galleries were packed long before the meeting started Stirring music was played on the great organ and as the chairman, Sir Watson Cheyne, came on the platform to the strains of *Rule Britannia* the audience rose and sung lustily The platform party included Sir William Osler, Dr F J Smith, and many other consultants The audience was emotionally labile—roars of applause, shouts of "No, No," "Never," cheers and groans Sir Victor Horsley had a particularly hot reception Amid shouts of "traitor," "Did Lloyd George send you?" he was refused a hearing Sir William Osler took a poor view of the behaviour of the audience and wrote to the *British Medical Journal* to that effect

The organisers of the Queen's Hall meeting followed it up by founding the B M A Reform Committee, the object of which was to 'ginger up" the B M A and to "end or mend" the council

Meetings followed one another at a great speed The South Western branch of the B M A held one at which no less than 38 resolutions, amendments, and riders were proposed and often voted upon The B M A Reform Committee opened an office in London and called for funds, their object now being to get counsel to draft an amending Bill Doctors in Poplar pressed a Poplar Medical Union to look after their local professional interests A meeting of Socialist doctors was in favour of a properly organised State Medical Service, but regarded the National Insurance Bill as the next best thing for the time being

Since Dec 16 when the Bill had become law it seems that some of the less belligerent were beginning to wonder whether the profession was really likely to defeat the Government Thus a well attended meeting of the Hampstead division by a small majority failed to demand the resignation of the council or to refuse to work under the Act The Sunderland division also supported the B M A as against rebellious organisations, as did the South Midland branch On the other hand the rebels were still active, and the B M A Reform Committee outbid the six cardinal points of the B M A with a programme of eight points

Mr Lloyd George was not slow to respond to the attacks launched by the profession On Feb 12, 1912, in the London Opera House he addressed a primarily Liberal audience His attitude towards the doctors and the B M A was more conciliatory than that of his audience, to judge by interjections, such as "Hang the doctors" He did, however, point out that in the event of the doctors boycotting the Act, the Government had large "suspensory powers" and would be obliged to hand over the funds for medical benefits to the friendly societies, who would then be free to bargain with the doctors individually—bargaining in which the doctor would be likely to come off worst

On Feb 20, 1912, a Special Representative Meeting of the B M A was held in Guildhall, London The first business was a motion that the chairman, Dr Maclean, be asked to resign the chair After a very long discussion —more in sorrow than in anger, as far as Dr Maclean's critics were concerned—a card vote supported Dr Maclean by 78 to 63 Furthermore a proposal that the council should be instructed at once to cease negotiations with the Government and the Insurance Commissioners was defeated What amounted to a vote of censure on the council was not carried Evidently representatives were beginning to be exhausted by the length of the meeting, for Dr Helme, an advocate of drastic action, alluded to "empty benches"

Meanwhile there was increasing disquiet about the Defence Funds or rather the inadequate response to appeals This is reflected in correspondence in the *British Medical Journal*, where the fund is sometimes—perhaps rather unfortunately—referred to as a "strike fund" The B M A circularised branches and divisions asking for guarantees and subscriptions, but without it seems much success

By mid 1912 the appointed day for the inauguration of the medical benefits section of the Act was only six months off If, as seemed probable, the Government were not going to give way, and the medical men stood by their pledges not to accept service under the Act, it was essential for the profession to have plans for the future In June, 1912, the State Sickness Insurance Committee of the B M A produced two alternative schemes for a Public Medical Service The main difference between the two schemes was that one was based upon a capitation system of payment, while in the other there was to be payment per attendance Both schemes were to work on a regional basis and were to be entirely under the control of the medical practitioners in the area The fees—a few pence weekly—were to be collected by collectors on a salary and not a commission basis Later two further alternative schemes were produced, but it is unnecessary to go into details, for all turned out to be castles in the air

Eclipse of the Moderates

The continued pressure of members holding extremist views, and the formation of what were almost rival bodies, such as the National Medical Union, encouraged the B M A to adopt a more determined attitude The *British Medical Journal* of June 22, 1912, warns members that they must not accept appointments on provisional insurance committees formed under the Act, nor even accept medical appointments in the sanatoria under the Act

Attempts were made to bring pressure on consultants and practitioners The latter were urged to employ only those consultants who had signed the pledge Every doctor was pressed to refuse to employ as a locum-tenens or an assistant anyone who had not signed Honorary staffs of hospitals were told to limit appointments as house officers and registrars to those who had signified their adhesion to the policy of the association Moreover the original undertaking, signed in 1911 by some 27,000 practitioners, was judged to be not wide enough, and a new pledge was circulated for signature This so called "pledge complementary to the undertaking" bound its signatories to place in the hands of provisional medical committees their resignations from every form of contract-practice appointment These resignations would be handed in when the State Sickness Insurance Committee judged the time to be ripe

The much-abused council having learnt from the Smith Whitaker episode the danger of making decisions submitted to the divisions and Representative Body alternative sets of recommendations

1 Breaking off negotiations
2 Continuing negotiations

At the Annual Representative Meeting held on July 19, 1912, there was long discussion of these alternative policies put forward by council, and with some minor qualifications it was decided to break off negotiations

One suggestion made, which indicates the strength of feeling among representatives, was that the General Medical Council should be approached with a view to their dealing with "blacklegs" as guilty of infamous conduct It was also proposed that the names of those members of honorary staffs of hospitals who had not signed the supplementary pledge should be circulated to secretaries of divisions Fears of actions for libel negatived this suggestion

The Last Three Months

The turn of the tide may be said to have come on Oct 23, 1912, when Mr Lloyd George addressed a conference of the Advisory Committee In an able and conciliatory speech he reviewed the types of medical practice among the industrial classes He felt that in many cases contract practice was underpaid and announced that, largely as the result of advice from the eminent medical men on the Advisory Committee, the Government had decided to increase the remuneration The suggested rate of 6*s* including drugs was raised to 9*s* for each insured person Of this 9*s* the sum of 1*s* 6*d* would be for drugs and 6*d* as a reserve to cover cost of drugs, if these exceeded 1*s* 6*d* If, however, this sum was not exceeded, the extra 6*d* went to the doctors

Although the Chancellor's offer did not come up to the demands of the B M A—i e, 8*s* 6*d* per insured person per annum, exclusive of drugs, it was a great advance on the rates paid by friendly societies for contract practice and clearly went a long way towards placating practitioners in the industrial areas

It was soon apparent that a more conciliatory attitude was developing A large private meeting of practitioners held in London on Nov 5, 1912, urged negotiation The correspondence pages of the *British Medical Journal* included many letters counselling negotiation and acceptance of the Government terms

The B M A extremists, and even more the rebels such as the National Medical Union, failed to see the red light At a special Representative Meeting in London on Nov 19, 1912, a motion to refuse to work the Act was carried by an overriding majority, but it was decided to appoint five members to interview the Chancellor These five were to report to the State Sickness Insurance Committee, who were to report to the B M A council who in turn, if necessary, were to refer questions at issue to the divisions of the B M A This lengthy procedure seems to bear out Mr Lloyd George's complaint that negotiation with the doctors was difficult if not impossible because no one body or committee was ever given power to bargain or negotiate

The interview between Mr Lloyd George and the five selected members of the B M A bore no fruit, and the council put the following question to divisions

> "*Are you in favour of the Association* calling upon the profession to refuse to enter into any agreement with local Insurance Committees to give service under *the Act* upon the terms and conditions now finally offered by *the Government* ?"

The council asked that returns from all divisions should be delivered to the central office by Dec 16, 1912 The results of the voting, published in the *British Medical Journal* on Dec 21, 1912, were

For refusal to serve	11,219
Against refusal to serve	2408

The total number of doctors who voted, including both members and non-members of the B M A, was 13,627 The number who had signed the B M A undertaking and pledge was 27,400 This suggests that half of those who had signed pledges abstained from voting

Meanwhile schism was spreading An organisation known as the National Insurance Practitioner's Association met in London on Dec 13, 1912, with Dr Lauriston Shaw in the chair It was attended by some 300 to 400 doctors The object of the association was to protect the interests of doctors who desired to accept service under the Act

A Special Representative Meeting on Dec 21, 1912, offered scope for fighting speeches on both sides, but the meeting voted in favour of refusing service under the Act by 182 to 21 amid loud and prolonged applause

The appointed day was now only three weeks off The Christmas truce was barely over when, on Jan 2, 1913, Mr Lloyd George announced that already nearly 10,000 doctors had joined the panels In districts where there was a shortage, he said, it might be necessary to close the panels temporarily and install a salaried service Fortunately these drastic measures never became necessary, as more and more doctors placed themselves on the panel

The die-hards still had a last fling On Jan 7, 1913, the London Medical Committee organised a protest meeting at the Queen's Hall with a former Lord Mayor, Sir Thomas Crosby, in the chair, supported by many well known consultants After patriotic music on the organ, Dr E B Turner and others denounced the Act and particularly Mr Lloyd George, who was likened to a "malign comet with a daily lengthening tail of inconsistent statements, repudiated utterances and promises unfulfilled"

The end was now in sight In all areas doctors hastened to join the panels, and in a debate in the House of Commons on Jan 7, 1913, Mr Lloyd George announced that 15,000 doctors had accepted service under the Act

The final scene was enacted at the Special Representative Meeting on Jan 18, 1913, when a motion to release all practitioners from their pledges and undertakings and was passed by 115 to 35 divisions In actual fact a majority of those concerned had already released themselves

It is interesting to speculate whether more favourable terms might have been obtained had the B M A taken up a less dictatorial attitude There is little doubt that the Chancellor handled the problem with consummate skill The appointment of the Medical Secretary, Mr Smith Whitaker, as deputy chairman of the commissioners split the B M A into two factions, the unexpected raising of the capitation fee pacified many of the moderates, and a few threats at the end rapidly filled the panels

The aphorism that history repeats itself is far from being always true The circumstances of every problem or dispute must necessarily differ widely, depending on the personality of the actors, the attitude of the spectators and the period in which the stage is set But the circumstances of the present dispute have some points in common with those of the days of the National Insurance Act of 1911 In each the public and the press were and are on the whole critical of the standpoint of the doctors The proportion of the profession engaged in general practice is considerably lower than in 1911, being probably not much over 25% The number of those looking for opportunities to get into general practices is large and many of these have spent long and sometimes depressing periods as assistants and trainee assistants Perhaps, however, the most striking difference between 1911 and today is that Mr Lloyd George was offering members of the medical profession entry into a new service, whereas in 1957 they are being asked by the B M A to consider resigning from an established, paid, and pensionable service

Conference

HUMANE TECHNIQUE IN THE LABORATORY

If we decide that experiments should be performed on living animals, it is our duty to ensure that their suffering is the least possible At a symposium held in London on May 8 by the Universities Federation for Animal Welfare (UFAW) with Prof P B MEDAWAR, F.R S, in the chair, the theme was that suffering could be reduced, and the value of experiments simultaneously increased, by *replacement* of animals by other systems, by *reduction* in the numbers used, and by *refinements* in technique

Major C W HUME, the secretary-general, opened the proceedings with a comparison of the warm-blooded and cold-blooded aspects of war and of experiment Thus the general might consider his soldiers, and the scientist his animals, as units or as individuals To neglect the warm blooded aspects was not only callous but incompetent, he pointed out that the soldier who is not cared for may fight less well, and he quoted Starling as saying that many experimental results were vitiated because the physiological effects of pain had not been eliminated

Dr W LANE-PETTER said that now about $2^1/_2$ million laboratory animals were used in this country each year, and the number was increasing by nearly 8% annually; we must plan for future needs He thought that bad husbandry was responsible for many losses—an interpretation which was criticised in the discussion Miss PHYLLIS CROFT, PH D, said that a humane technique involved asking such questions as "Is the experiment necessary? Has similar work been done before? Is the technique appropriate? Are the numbers and method such that most knowledge will be gained from the fewest animals? Can animals be replaced?" She drew attention to the importance of properly trained technicians, and to unnecessary suffering caused by, for example, delayed euthanasia and inappropriate housing conditions (e g, cats and mice in cages in the same room) The pulse-rate and electrical resistance of the skin could be used as a measure of pain suffered by animals Answering a question, Dr CROFT said that the definition of a necessary experiment must be left to the integrity of the experimenter The chairman suggested that an experiment prefaced by "I wonder what would happen if ?" is usually not necessary Mr W M S RUSSELL, D PHIL, pointed out that the experimental animal was usually a model for the human It was irrational to suppose that the animal nearest to the human was therefore the most appropriate, for certain other (e g, electronic or bacterial) models might eliminate variables A general theory was needed to decide where and how replacement of animals, especially mammals, was indicated

The next three speakers described ways of replacing animals Mr G SYKES said that, for assay of B vitamins and amino acids, microbes were often more sensitive and convenient than mammals He spoke at length on these techniques Mr F. K SANDERS, *D PHIL*, spoke as a virologist Animal tissues (egg and tissue cultures) could be used for growing viruses, they had not the disadvantages of antibody formation or the presence of latent viruses In tissue cultures, moreover, cytopathogenic effects were sometimes specific Contamination could be satisfactorily suppressed by addition of penicillin, streptomycin, and nystatin, and tissue-cultures could now be bought commercially He described an ingenious method of counting viruses using a tissue culture in a plate and vital staining, so that dead groups of cells (i e, those infected by virus) showed up as pale spots He pointed out that one animal, painlessly killed, could provide 20 plates of cells, and 4000 units of information of greater precision than would be possible using 4000 animals Mr W Grey Walter, Sc D, spoke of the "artificial zoology" thriving in many centres in Europe and America He gave a brief, stimulating, and lively account of his models of segments of nerve, of "*Machina speculatrix*," with its two reflexes, and of Cora, the conditioned-reflex analogue, which can behave neurotically His electronic "animals" and preparations were useful for investigation and especially for teaching When they broke, he said, they did so with a loud clear bang

The conference then turned to means of reducing the number of animals used Major Hume explained the fallacy of assuming that using a large number of animals always gave a truer picture it might introduce error by including a more heterogeneous population Statistical methods would give more reliable results and allow the use of fewer animals He said that wide difference in the responses of patients would swamp small inaccuracies in the assay Dr Lane Petter discussed the genetic foundations for producing animals as nearly uniform as possible, and Mr M R A Chance, Ph D, described the profound effects on the physiology of rats of minor environmental changes, such as altering the number in a cage The conditions making for uniformity were those in which the rats were happiest In the discussion, it was pointed out that the law required high accuracy in bio-assay, even though variations in clinical response often made such accuracy unimportant in practice

The final section of the conference was devoted to humane refinements in technique Dr Chance insisted that the environmental conditions, the response, and the units in which they are mentioned must all be specified, or the work could not be repeated He pointed out that rats normally slept by day and ran a lot, and that their metabolism was adjusted accordingly, this must be allowed for Dr Croft gave an account of methods of anæsthesia, emphasising technical points to reduce fear (such as full preparation to eliminate delay at the start, and the avoidance of regional anæsthesia where possible) She warned against dangers peculiar to modern techniques—e g, species difference in synergism where several drugs were used, and the possibility of an animal waking up while paralysed by a relaxant Activity too early after a relaxant might lead to muscular pain Dr Russell discussed ingenious means of refinement where this might seem impossible—i e, in experiments on stress itself For instance, certain birds would not approach another of the same species except to mate, and then the male approached the female with a pivoting action, of which the turning away component was an avoiding reaction and a sign of stress Such birds could be used to test the effects of a drug designed to combat fear

In the discussion, Mr A L Bacharach said that, in view of species differences, tests of toxicity might appropriately be confined to one species, for the effect in man might still be different even if many species were used Other speakers mentioned the unfortunate impression that would have been gained from tests of histamine confined to rats or, conversely, of penicillin confined to guineapigs, and emphasised the need for good animal technicians An excellent 16 mm sound film (which may be borrowed free from UFAW, 7a, Lamb's Conduit Passage, London, W C 1) was then shown, demonstrating methods of handling the common laboratory animals

In England Now

A Running Commentary by Peripatetic Correspondents

I suppose there has always been in medicine a kind of Priest of the Grove whose name could be invoked when the inexplicable had to be explained or a "cause" adduced for the "idiopathic" Evil spirits, witchcraft, planetary influence (immortalised as influenza), miasmata, and the like have reigned and been displaced In our own time auto-intoxication, -ptosis, the septic focus, hypovitaminosis, endocrine imbalance, and allergy have donned the mantle and either lost it altogether or found moth in it They come and go but we can't do without them, a Word of Power we must have Now that the glint in Allergy's eye is fading a little, "Stress" seems to be shaping nicely for the succession He's a promising candidate, so pleomorphic, almost like Proteus, but I wonder if he isn't overreaching himself a bit He's gone adjectival, sprouted a hyphen, and is claiming as his own a whole bunch of maladies which but yesterday owed allegiance solely to Allergy or else went about as free and independent morbid entities He calls them "Stress diseases" They include, I am almost sure, asthma, migraine, thyrotoxicosis, gastric and perhaps duodenal ulcer, eczema, urticaria and the neurodermatoses, ulcerative colitis, rheumatoid arthritis, and many of their friends and relations

"But what *causes* it, doctor?" "It's a stress disease, Madam" Most satisfying to both parties! So pleasant in its implications! But true and going to last? I wonder Take my teichopsia—surely no less a member of the band than migraine True, it first appeared under the mild stress of writing what I fondly hoped might be a prize essay, but it didn't stop me nor, I am sure, did I blame it for my ill-success In forty-five years since then it has appeared perhaps half a dozen times Stresses there have been, too—traumatic, bacterial, circumstantial, professional, familial, personal How could there not have been? But never have stress and spectrum come together or had any perceptible time-relation The same goes for asthma If sleeping under the stars on a lawn or on the deck of a moored yacht during a blissfully happy summer holiday was "stress," then, of course, the case is clear enough But was it? Forty years back I was asked to accept the view that "happy people don't get Graves's disease" and I was very ready to do so But when I put the proposition the other day to a physician, surgeon, and registrar at a world-famous thyroid clinic they would have none of it

I'm almost sure that if Stress is wise he will drop his hyphen and take his place quietly by the side of Constitution and Fate, much as he may dislike their company

* * *

It took a great deal of my professional and spare time to perfect my two-finger-action distance-controlled modification to the hypodermic syringe It really was a delightful contrivance, a gleaming chrome, sparkling stainless-steel, extended plunger—and strong too My big worry was whether anybody else had invented or, worse, even patented it, because I liked to think of my name being perpetuated by thousands of doctors through the ages each time they said "Sister, please hand me the syringe with Gubbin's modification" In essence, it allowed a doctor, or the patient, himself, to give an injection from a distance The long flexible extension to the plunger of the syringe would enable an anæsthetist, for instance, to continue an injection into a vein in the dorsum of the foot without moving away from the head of the patient The fact that it was a little stiffer when used at its full distance prompted me to seek perfection and ask for the help of our local scientific and optical instrument-makers

I must admit I was a bit narked when it was returned attached to my camera (which they had taken ages to repair) as a remote-control trigger

* * *

The machine which Willie Bill operated was about the size and dimensions of a shop-front, and quite dwarfed Willie Bill, who was a wispy youth with a weary stance and a semi detached mandible His teachers had described him as bone-idle, and his family as one who was "nobbut tenpence to t'shillin'" But Willie paid as little attention to them as to anything else outside the local cinema

He had decided that he resembled Elvis Presley, refused to have his hair cut, and lowed dismally and adenoidally through most of his working day Luckily for his workmates, Willie Bill's machine made much more noise than Willie Bill It was his task to supply it with slabs of heavy cardboard, which he pushed into a large horizontal slot at the level of his waist Once they were inside, a powerful knife descended and sliced them into shape Its designers had provided the machine with every safety device they could think of, but what they hadn't thought of was that Willie Bill would lash up these devices with bits of bootlace to stop them getting in his way Everybody, from the Chairman of Directors (who had attended night-school with Willie Bill's father) to Dan'l Hargreaves the overlooker (who happened to be Willie Bill's uncle), had spoken severely to Willie Bill about such recklessness "Tha'll be workin' this here cutter single-handed yet lad," said Dan'l grimly on several occasions while undoing his nephew's handiwork Willie Bill's mates contented themselves by laying bets on how many fingers, and when, and by asking him at the end of a shift if he could still count up to ten without taking his boots off

About three feet above Willie Bill's head the machine had a shelf-like projection upon which he assembled his collection of pin-up girls By cricking his neck he could gaze rapturously at these delights It was to move Miss Diana Dors to a more delectable angle that Willie Bill climbed on to the lip of the slot where the cardboard was inserted, and unwisely poked his toes inside

I hurriedly left my lunch and arrived at Willie Bill's house to find him reclining on the sofa in the front room with both his feet swathed in bandages He held a pint pot of tea in one hand and half a teacake in the other and was telling the tale to an enthralled "fan-club" of neighbours Having cleared the front room, I removed the factory first-aid man's excellently applied bandages from Willie Bill's feet the only damage was the loss of the terminal half-inch of both great-toes "Ah wouldn't mind so much," said his mother, relieved and angry, "if he hadn't gone to work in his new socks"

But Willie Bill really had the last word "It 'ull make them at t'Works look a bit silly, will this 'ere," he said, waving his teacake complacently, "me gettin' me toes chopped off when they've allus been sooa cocksure it 'ud be me fingers"

* * *

Queer thing about the babies I see nowadays—they are ravenous Their appetite is phenomenal, really, but as it is so common we don't wonder at it In the old days a baby was expected to double his birth-weight at six months Now they often double their birth-weight at three months—some even at two You just can't shovel the food into them fast enough "Self-demand feeding" we primly term this stoking-up process Of course nowadays many expectant mothers go on to diets —some as low as 1000 and 1200 calories, I'm told Are the babies being born too hungry? In the old days the antenatal mothers were on self-demand (unless toxæmic or what-have-you) and the babies went on a rigid schedule Now the expectant mothers go on a rigid schedule and the babies are on self-demand

THE JUNIOR HOSPITAL MEDICAL OFFICER

Broke, broke, broke
  Once more in the red I see
And I would that my tongue could utter
  The thoughts that arise in me

O well for consultants, part time,
  O well for the rich G P
Whose car expenses, and carpets, and maids
  Are covered by Schedule D

O well for the hospital cooks,
  The porters, the stokers, the chars
Who draw double pay for their work at weekends,
  And roll away home in big cars

But woe for the J H M O
  With no political powers—
For eight hundred quid he must travail a year,
  Be on call all the twenty four hours

Letters to the Editor

RADIOLOGICAL HAZARDS TO PATIENTS

SIR,—A committee was set up last year by the Secretary of State for Scotland and the Minister of Health "to review the present practice in diagnostic radiology and the radiotherapy of non-malignant conditions, with the object of considering the hazards involved"

This review was recommended by the Medical Research Council in their report on *The Hazard to Man of Nuclear and Allied Radiations*, for they found that medical radiology is in fact the chief source of the extra radiation to which we are now exposed They emphasised the genetic damage which might be caused by irradiation of the gonads, and it is this damage with which our committee is chiefly concerned Its importance is difficult to assess, but it means that we must not neglect even very small sources of radiation

Since I fear that our inquiries are bound to add to the work of busy people I hope you will allow me to describe the investigations which we have in mind. Our first requirement is a more accurate estimate of the amount of gonadal radiation over the whole population, for the genetic hazard depends ultimately on the total rather than on the individual dose and we must know the present figure if we are to keep in touch with future developments To obtain such a base line we need a survey of the total number and type of X-ray examinations carried out within a given period, followed by estimations of the gonadal dose in a representative sample

We have already sent out detailed questionnaires to make a census of all medical and dental procedures involving X rays and radioactive substances, and a similar more limited inquiry will be made six months hence to take care of any seasonal fluctuations which might affect the result To measure the probable dose to the gonads in different radiological procedures we are asking a number of hospital physicists to make a detailed investigation in a sample group of about 100 hospitals This will enlarge the excellent surveys which have been carried out already in particular departments, and when it is finished we shall have a figure for the total gonadal radiation in this country which should be at least more accurate than any former estimates, here or elsewhere

We are told that any exposure of the gonads may induce some mutations and that all mutations are more likely to be harmful than beneficial But medical radiology must not be unduly hampered the possible harm to the race must be set against the certain benefit to the individual We must aim, however, at reducing all unnecessary exposure of the gonads and with this in view the committee has formed small specialist groups which are to consider individual procedures in different clinical fields and to suggest measures for improving their safety

In seeking through your columns to put this information before the profession as a whole, my committee hopes to enlist the interest of all those whose work touches on the use of X rays and radioactive substances We are fully aware of the inconvenience and extra work we are causing and we have learnt with regret of occasional failures in our arrangements for giving notice of the survey But we believe that the final result will justify what we are doing We live in a period when a rise in the level of man made radiation cannot be ruled out and ought not to go undetected It is disturbing to think that medical radiology may be causing unnecessary exposure of the gonads and that it may cause more if we take no steps to measure the present level We hope that all doctors and dentists will cooperate with us in our work

VACCINATION AGAINST POLIOMYELITIS

SIR,—There is at the present time serious anxiety in both the medical profession and the general public about the failure of the programme to protect our population against poliomyelitis by vaccination; this anxiety has now found voice in the national press. Why, it is asked, in view of the shortage of vaccine produced in this country, is our inadequate supply not supplemented from the U.S.A. and Canada, where it is plentiful? It may be useful to review the relevant facts.

The principle of vaccination against poliomyelitis was accepted over a year ago, when we were told that children in the age group 2–9 years would be the first recipients, and that it was expected that 2 million children would receive the vaccine in the first year. In the event, not 2 million but rather less than 200,000, or approximately 1 in 30 of the 6 million children in this age-group, received their first two doses last year, and this year doses for only 500,000 children have so far been released—after considerable doubt whether they were, in fact, safe. In spite of official optimistic pronouncements future supplies are still uncertain, since the next batches have not yet passed the safety and efficiency tests and like previous batches may have to be thrown away.

The poliomyelitis programme introduced with such rejoicing has, in fact, failed dismally. There can, indeed, hardly be said to be a programme at all; not only has the age group selected for protection last year not received the promised vaccine, but the equally, or perhaps more, urgent claims of other groups have not even been considered. Particularly noticeable has been the failure to meet the pressing needs of persons in particular danger of contracting the disease because of either increased susceptibility or increased exposure. In this connection one must mention the urgent need to protect expectant mothers (because of their particular susceptibility), doctors and hospital, nursing, and ambulance personnel (because of their particular exposure), and, of course, persons travelling to areas of high incidence, notably Service personnel and their families, all of whom contribute disproportionately to the quota of fatal and severely paralysed cases claimed annually by poliomyelitis.

The failure of the vaccination programme is attributed to difficulties, not unexpected, in the production of British vaccine.

> Only two firms are making vaccine in this country. They are struggling gallantly with the difficulties of a process with which they are unfamiliar—difficulties increased by the generally admitted lack of virological facilities in this country at the present time. One firm has so far not produced any vaccine at all, though it hopes to be in production by the summer; the other has produced the small amount of vaccine so far issued by the Ministry of Health. Both firms are working under stress of urgency, which cannot be conducive to the best long-term results, and it is no secret that the manufacturers, through no fault of their own, are having to throw away whole batches of vaccine as unsafe or unsatisfactory, with the result that the amount of vaccine available falls short of forecasts.

But why must our programme be confined within the tiny limits of British production, when there is already a vast production capacity of vaccine, well-proven for safety and efficiency, in the U.S.A. and Canada?

Since the initial Cutter incident in 1955 led to tightening of the control on production and testing, over 60 million persons have received Salk vaccine prepared in the U.S.A. and Canada, and the safety of the production and testing of vaccine in those countries must by now be accepted as unimpeachable. In addition, both epidemiological and laboratory findings confirm the effectiveness of Salk vaccine in preventing paralytic poliomyelitis. An obvious solution to our problem is to supplement our own inadequate supplies of vaccine with imported vaccine from the U.S.A. and Canada. We have, in fact, been assured that, should we apply for it now, we could receive immediately sufficient vaccine to protect at least 4 million people, and that further supplies could follow after a short interval. Why then can doctors in this country not obtain this well-tried vaccine, either under the N.H.S. or by private purchase?

We are assured that commercial considerations, dollar currency restrictions, and internal economy could, none of them, be allowed to influence the decision against the import of vaccine. Yet what else can explain that it is impossible for firms to get an import licence for vaccine of the highest repute, which must be regarded as an essential substance for the prevention of paralysis by poliomyelitis? Its import is, in fact, prohibited not only by dollar restrictions, but also in the Therapeutic Substances Regulations.

Semi-official statements have suggested as an excuse that American and Canadian vaccines are not safe, because the type-I strain used in their preparation is the Mahoney strain and it was the Mahoney strain which, because it had not been killed, was responsible for the Cutter incident in 1955. The Cutter incident occurred because batches of vaccine were inadequately tested before they were used and live virus was present in the vaccine. The whole purpose of the improved production methods and safety regulations introduced after the incident was to ensure that (*a*) the testing machinery should not be by-passed and (*b*) the testing procedures should be as safe as human ingenuity could devise. The successful vaccination without incident of over 60 million people bears witness to the fact that both objectives have been achieved and that Salk vaccine is a safe weapon against poliomyelitis. It is, of course, not so much the virulence of the strains used that matters, as the guarantee that all three strains—of types I, II, and III respectively—are killed before the vaccine can be issued for use.

The large-scale, smoothly running production and testing procedures so carefully developed and well tried in the U.S.A. and Canada must be regarded as second to none in the world. Certainly they are not second to those at present in use in this country, where manufacturers, however able, must be regarded as working under very difficult conditions.

The alarming rise in notifications for poliomyelitis in the first quarter of this year stresses the urgency of our need for vaccine *this year*. Last year the notifications were comparatively low and the high figures this year must be regarded, not as the overspill of last year's epidemic, but as the beginning of a severe 1957 epidemic. No one can be sure that we are going to have a severe epidemic this year, but the signs are bad and, certainly, no one can say that we are *not* going to have one. Already we are admitting to this hospital, at what should be our slack period for poliomyelitis, an unusual number of fresh cases with severe *permanent* respiratory and locomotor paralysis. Some of them are in the 2–9 age group, who should have been protected last year; others are from outside this age group, illustrating in their tragedy the hopeless inadequacy of a programme confined to an age group which provides rather *less* than half of the fatal and severely disabled cases occurring annually in this country.

Medical officers of health and general practitioners assure me that, could they receive vaccine now, there would be no delays in its injection. General practitioners, the school health service, infant welfare clinics, antenatal clinics, hospital personnel, and Service doctors could combine in an "operation vaccine," which would ensure protection of all the priority groups and a high proportion of the rest of the population within three months and would undoubtedly cause a dramatic fall in notifications, and save many at present destined for death or paralysis.

In taking his decision on the import of vaccine, the Minister of Health must weigh the risks carefully: on the one hand, the theoretical danger of using American vaccine, already well-tried, and trusted not only by the distinguished American and Canadian virologists and epidemiologists concerned in the vaccination programmes in their countries, but also by their counterparts in other countries in Europe, South Africa, and South America, now importing Salk vaccine for the protection of their populations; on the other hand, both the *certainty* that, unless this vaccine is used, the homes of thousands of adults and children will suffer the disaster of poliomyelitis this year, as they do every year, and the *possibility* that we are, in fact, at the beginning of a severe epidemic, such as this country has not yet experienced, but which we cannot, without vaccine, hope to escape much longer. These risks are the only considerations which can weigh in the Minister's decision. Not dollar restrictions; not internal economy (the cost of the prevention of poliomyelitis will in one or two years be redeemed by the saving of the, at present appalling, cost of the care and support of the permanently paralysed); not the hurt pride of technical advisers; not a misplaced loyalty to British products; above all not the desire in some "research" quarters to carry out "controlled studies" of the incidence of the disease in the vaccinated and the unvaccinated, must be allowed to weigh with a Minister whose primary concern is the care of the nation's health.

The announcement that vaccine is to be imported freely, to supplement our present inadequate supplies, would give tremendous relief to an anxiety which is rapidly becoming intolerable.

No one, of course, need accept vaccine, British or American, if he does not wish to; but at least the protection will be available. The important step is for the Minister to apply immediately for allocations of the exportable surpluses of vaccine of the U.S.A. and Canada, and to remove the currency and the import restrictions that are at present depriving our population of access to an essential medical preparation. Whether the Ministry of Health can be persuaded to sponsor a nation-wide campaign for the unlimited free vaccination of our population against poliomyelitis, or whether it is left to the initiative of general practitioners, medical officers of health, and those concerned with the care of specially exposed groups to purchase the protection out of other funds is a question secondary to the main issue of the availability of supplies of vaccine, sufficient to give protection now to all who want it, before the annual toll of tragedy is claimed by this now preventable disease.

PULMONARY HYPERTENSION

SIR,—With reference to your leading article of May 4, we are surprised that you have once again omitted any reference to our paper on Patent Ductus Arteriosus with Pulmonary Hypertension.[1] In it we presented clinical material showing the possibility of reversal of severe pulmonary hypertension following ligation of the ductus. In an earlier letter[2] we drew your attention to our paper, following the omission of reference to it in your leading article on Patent Ductus Arteriosus.[3] We feel that the results we recorded are relevant to the discussion in your recent review of pulmonary hypertension.

RELATIVES IN HOSPITAL

SIR,—I was most interested to read your leading article last week. I agree that medical students are at a great loss as they are rarely able to talk to the relatives of their patients. In Birmingham an attempt has been made to remedy this by inviting the students to be present when the consultant sees the relatives. At these meetings it is explained to the relatives that all that are present (houseman, ward sister, almoner, and students) are looking after their relative while he is in hospital and are anxious to learn the uncertainties in their minds and the social consequences of the hospital admission. After attending a few of these meetings the student finds that he can take a greater part in them. Unfortunately this scheme is not in general use here, but I think that it should be brought to the notice of those who are at present considering revision of the medical curriculum. The introduction of teaching along these lines would help to allay the fear of relatives that exists among junior hospital residents and thereby better the relationship between the hospitals and the general public.

NEONATAL DEATH AND ELECTIVE CÆSAREAN SECTION

SIR,—Last week's article by Dr. Strang and his colleagues was of particular interest to me as it provides supportive evidence for some of my speculative ideas on the production of the pulmonary syndrome of the newborn.

These workers plainly regard the existence of the "cæsarean-section syndrome" with profound scepticism because they have not been seeing it. I suggest that this is due to the excellent prophylaxis they have been practising, just as some workers rarely saw retrolental fibroplasia long before its cause was determined. I believe that the cæsarean-section syndrome can occur, for I have observed it. I also believe that it does not differ from the pulmonary syndrome of the newborn, except that it may occur in full-term babies, whereas it is virtually confined to premature deliveries when these take place per vaginam. This provides an important clue to its ætiology and strongly suggests that it is preventable. Finally, it is my belief that such apparently diverse pathological findings as pulmonary congestion and œdema, pulmonary hyaline membrane, intra-alveolar hæmorrhage, cerebral œdema, and cerebral intraventricular hæmorrhage may be inter-related and result from similar factors.

It seems to me that the important point in the immediate after-delivery care of these babies is the *delayed ligation of the umbilical cord*, as practised by Strang et al. and many other workers. This may allow time for respiration and expansion of the lungs to occur before the baby's hitherto sole supply of oxygen is cut off and harmful effects from acute asphyxia have resulted. It is also possible that the increased volume of blood obtained from the placenta may help to fill the pulmonary capillaries and assist in alveolar expansion.[1]

Believing that delayed onset of respiration is of paramount importance in the production of this syndrome, I should like to suggest a possible improvement in the resuscitation of these babies. Would it not be possible to apply the simple methods of resuscitation described, including gastric suction and, if respiration is not immediate, intragastric oxygen while the cord is still intact and pulsating? This might tide the baby over that dangerous period of anoxia between the loss of placental circulation and the delayed onset of respiration.

SENIOR REGISTRARS AND CONSULTANT APPOINTMENTS

SIR,—I hesitate to cross swords with so able a controversialist as my friend Dr Hubble I venture, however, to dispute his implication last week that "it is the way of English medicine" for a consultant to pass (so far at least as hospital work is concerned) straight from a state of pupillage to one of complete responsibility Surely it was the custom, in most of our teaching hospitals and in many of the large non teaching voluntary institutions, for a newcomer to the then honorary staff to be appointed in some such grade as that of assistant physician or assistant surgeon In the case of Dr Hubble's own parent hospital, I seem to remember reading the tribute paid on retiral by Lord Horder to one who had long been his junior, Dr A E Gow

I am not here concerned to argue whether what has happened in the past should, under new conditions, continue to happen in the future But I do think it important to establish clearly what did happen in the past

University of Sheffield J G McCrie

FÆX

SIR,—Dr Derbes, in his letter last week, overlooks the possible confusion between "fæces" and yeast (*fæx siccata*), sometimes, but not I think now often, used for the more modern *cerevisiæ fermentum* Perhaps the use of the word *fæx* for yeast is not known in the U S A

London, W C 2 George B Kilgour

TREATMENT OF HIRSCHSPRUNG'S DISEASE BY SWENSON'S OPERATION

SIR,—I was interested to read the article by Mr G G Wyllie (April 27) on the management of 152 cases of Hirschsprung's disease by rectosigmoidectomy The argument put forward for this type of operation is now well established, but I was perturbed at the degree of bowel disturbance after a successful operation Mr Wyllie says that treatment for constipation was required in 34 cases The constipation was caused either by failure to appreciate the sensation of a full rectum or by "colonic inertia" due to leaving in situ the considerably dilated non-diseased colon Moreover, of 102 children over 3 years old, 41 had lack of full rectal control with some incontinence, and the number with enuresis was higher than would normally be expected One gets the impression that the results are not as good as one would hope for on theoretical grounds

Therefore I feel that some mention should be made of State[1] in Minneapolis, who treated a series of 16 patients, with very satisfactory results, by left hemicolectomy, removing dilated bowel and the "physiological stricture" in the rectosigmoid He doubted whether the ganglion theory was the complete answer, and felt that the dilated colon might be the abnormal lesion, perhaps of parasympathetic origin

State left the rectum in situ and thus did not disturb nervi erigentes Mr Wyllie makes no mention of the risk that pelvic dissection may cause impotence, but the follow-up period may not be long enough yet to assess adequately this factor This is not a theoretical risk, since mobilisation of the rectum in adults to remove cancer or long standing abnormalities carries a definite risk of producing impotence

The only criticism on theoretical grounds of left hemicolectomy is that recurrence, with further constipation, may follow incomplete removal of the aganglionic segment of bowel As constipation is common after the Swenson operation it would seem logical to allow the child to grow up to manhood, constipated or not, with the maximum chance of developing to normal "Kinsey standard" Nevertheless, as State's good results have been confirmed at this hospital, surely left hemicolectomy is worthy of a trial in the first instance, even if Swenson's operation is done later—perhaps after many years

RELEASE OF HISTAMINE IN URTICARIA PIGMENTOSA

SIR,—Dr Hamrin (April 27) reported a case of urticaria pigmentosa in a patient who was sensitive to acetyl salicylic acid (aspirin) He raises the question whether intolerance to aspirin may be caused by histamine release and not a true allergic (antigen antibody) reaction Mast cells, which are found in large numbers in the skin in urticaria pigmentosa,[1] are very rich in histamine Any cellular injury, including mild trauma or an antigen antibody reaction, will release cellular histamine Aspirin sensitivity causing angioneurotic (Quincke) œdema is the commonest drug sensitivity seen in a general allergy clinic In a patient who is sensitive to aspirin and who has urticaria pigmentosa, the reaction is likely to be severe because of the large amounts of histamine that can be released I have seen 4 patients with urticaria pigmentosa who have later become sensitive to bee or wasp stings They reacted very severely when stung only after they had become sensitive The reaction in each case was a generalised urticaria, with difficulty in breathing and unconsciousness, in under five minutes In any proved case of urticaria pigmentosa it is advisable to ask whether there has ever been a severe untoward reaction (due to an induced sensitivity) following an injection (e g, penicillin), drug taking (e g, aspirin) or a sting (e g, by a bee) This association was described at the European Congress in Allergy last year[2]

A W Frankland

ANTIGEN-ANTIBODY RESPONSES IN MULTIPLE SCLEROSIS

SIR,—Your annotation of April 13 refers to work done at Oxford by Dr Honor Smith and her colleagues on this subject The mode of investigation was lumbar intrathecal injections of tuberculin The patients with this disease were all volunteers and, you state, "a control group of psychotic patients was used for comparison" Surely I cannot be alone in finding this state of affairs disturbing ? Even the experimental work with the diseased group may not be as permissible as appears on the surface Any patient with a progressive incurable disease will snatch at any procedure, however hazardous, offered with whatever explanations and reservations The pressure to volunteer is enormous as I know, with regret, from past errors of my own in this respect But allowing that the work was justifiable in this group, what are we to say about the psychotics who were submitted to an undertaking with considerable risks ? Were they volunteers ?

To experiment on patients who are fully aware of the situation and accept it is one thing—though I have indicated that even here there are reasons for caution To experiment on those who cannot understand what is happening, cannot give permission, cannot possibly benefit, and may suffer serious *consequences*, is quite another and calls for the severest *condemnation*

London, W 1 David Le Vay

*** We have shown this letter to Dr Honor Smith and Dr Ritchie Russell, whose reply follows —*Ed L*

SIR,—We sympathise with Mr Le Vay's sentiments, but he is inaccurate in suggesting that a dangerous experiment was carried out on mental patients—"who cannot possibly benefit, and may suffer serious consequences"—simply in order to provide controls for our observations on disseminated sclerosis. As the earlier papers quoted in our communication show, the observations on mental patients were made several years ago in the course of a study into the widely canvassed question of the possible parts played by tuberculosis and by alterations in the blood-C.S.F. barrier in the ætiology of mental disease. At the same time it was considered that the transient pyrexia and cerebral hyperæmia that accompany the reactions might well be beneficial in mental disease. In point of fact, the reactions were invariably well tolerated, no adverse results were ever seen, and the hazard was undoubtedly less than that incurred by, say, electroconvulsion therapy.

[1] Riley J F West, G B *J Physiol* 1953 120 528
[2] Frankland A W Proceedings of the European Congress of Allergology 1956 vol I, p 501

However, the lack of adequate volunteers is a constant hindrance to the research-worker, and doctors themselves often act as such. It might be well worth while to establish a Corps of Volunteers of those who are prepared to face a certain risk for the benefit of others.

SUBUNGUAL HÆMATOMA

SIR,—Surely much the most simple—and painless—method of dealing with this condition is, after the application of iodine, to break through the thin membrane at one corner at the base of the nail where it is stretched and taut through the nail being pushed up by the accumulation of blood underneath. This can easily be done with a sterile needle and the blood evacuated.

If blood re-accumulates, as is often the case, it is easy to repeat the process.

Leiston, Suffolk. D. G. GARNETT.

REDUCED EFFECT OF HETEROLOGOUS INTRINSIC FACTOR

SIR,—Since I have noted the same phenomenon as that reported by Dr. Schwartz and his colleagues (April 13), I should like to give a short account of my results.

In December, 1953, I started an investigation of an oral preparation containing hog intrinsic factor with vitamin B_{12} ('Bifacton,' N.V. Organon). 22 patients were followed for more than two years by serial blood counts and serum-vitamin B_{12} estimations, using *Euglena gracilis* as test organism. In most patients the serum vitamin B_{12} soon began to decrease. After varying lengths of time the levels became subnormal (less than 100 µµg. vitamin B_{12} per ml. serum). After that, hæmatological relapses became increasingly common.

After two years, 10 patients had relapsed, 5 had normal blood counts but subnormal serum-vitamin B_{12} (pre-relapse), and 7 were normal. Increasing the dose neither increased the serum vitamin B_{12} levels nor improved the anæmia. For example, one patient, who initially had a complete remission on 2 tablets daily, after eighteen months relapsed while being treated with 4 tablets a day. Each tablet contains 7.5 µg. of vitamin B_{12} and 0.5 oral *U.S.P.* units of factor. In the 10 patients who relapsed, the length of time between the first subnormal serum vitamin B_{12} value and the relapse varied from four to twenty-two months, with a mean of thirteen months.

A Schilling test, using 0.5 µC (0.5 µg.) of vitamin B_{12} containing ^{58}Co, was performed on 5 of the 10 patients in relapse. When the test dose was given with water the patients excreted 0–0.4% of the given dose. With bifacton intrinsic factor the corresponding urinary excretion ranged from 0.2 to 0.7%, but the excretion was increased to 7–23% when the patients were given a test dose in 100 ml. of normal human gastric juice.

At that time, I thought it might be interesting to know whether another preparation of intrinsic factor from the same animal would show the same phenomenon. Two of the patients mentioned above were tested with 'Bendogen' (Kabi). Both showed a normal excretion (14% and 23%). There was thus evidence that the refractoriness had been induced by the treatment.

A third patient already refractory to bifacton after treatment for twenty-two months was transferred to therapy with bendogen for two months. A Schilling test was then performed with water, bifacton, bendogen, and human gastric juice. The urinary excretion values were found to be 0, 0.6%, 2.4%, and 17% respectively.

I have treated 6 patients with bendogen who had a subnormal serum-vitamin-B_{12} following protracted bifacton treatment (pre-relapse cases). In all cases the serum-vitamin-B_{12} concentration initially increased to within normal limits. Then the levels began to fall as at the beginning of the bifacton treatment. 3 patients have now reached subnormal serum levels of vitamin B_{12}. I hope to be able to show a double refractoriness, both to bifacton and bendogen, in these cases.

In view of these experiences I do not consider oral treatment to be rational in pernicious anæmia.

These results were reported at the meeting of the Swedish Medical Society in December, 1956. A detailed account of the experiments will be published later.

Institute of Medical Chemistry,
University of Uppsala, Sweden.

ANDREAS KILLANDER.

MEDICAL STAFFS OF MENTAL HOSPITALS

SIR,—The letter from Dr. Strauss and others (May 4) is timely. Judging by the situation in this region, the comprehensive review of psychiatric services which they propose is urgently needed. In the Leeds Hospital Region, whereas the number of psychiatric inpatients has risen comparatively little (i.e., from 10,783 in 1948 to 11,347 in 1956) the admission-rate has *almost doubled*, from 2850 admissions in 1948 to 5400 (of which 74% were voluntary) in 1956.

There has also been a big rise in the number of new outpatients seen annually, from 1650 in 1948 to 3100 in 1955. In addition, the number of outpatient attendances per new outpatient seen has risen from 2.9 in 1948 to 5.5 in 1955. No data are available from which to estimate the increase of outpatient work since 1955, but the lengthy waiting-lists that have accumulated make it evident that the demand has far outstripped the provision.

In this region there has been some increase in the senior staff in the psychiatric hospitals in that, whereas there were 16 consultants and 10 senior hospital medical officers (S.H.M.O.s) in 1948, in 1956 there were 25 consultants and 19 S.H.M.O.s. The senior staff has therefore risen from a total of 26 to 44. Nevertheless, even with this rise, the current senior-staff/inpatient ratio is still only 1/258. When it is borne in mind that these psychiatrists, in addition to the treatment of inpatients in psychiatric hospitals (whose admission rates have doubled since 1948) have to provide the outpatient services, which have expanded equally greatly, it will be evident that their numbers are inadequate to enable them to devote as much time as they would wish either to the treatment of individual patients, whether acute or chronic, inpatient or outpatient, or to the training and supervision of their junior colleagues.

Department of Psychiatry,
University of Leeds.

G. R. HARGREAVES.

SIR,—Dr. Strauss and others rightly emphasised the need for an increase in the medical staffs of mental hospitals. There is also need for increased facilities for outpatient electroconvulsion therapy, which would reduce the overcrowding in most admission units, benefit the patients, and result in a substantial economy to the National Health Service.

The increasing number of patients attending psychiatric outpatient clinics is not altogether a reflection of the success with which they are being treated. It arises as much from the changing conditions of general practice, too well known to need repeating. A large proportion of these patients would, however, be better dealt with by their general practitioner, familiar as he is with them over long periods of time. The lack of special training in psychotherapy should not deter him. Few psychiatrists have had any either, and at the level at which it can be given in outpatient departments this is unlikely to be of any significance

Glengall Mental Hospital
Ayr
HARRY B MILLER

SIR,—Having read the important letter by my revered teacher Dr Strauss and his co signatories I should like to make a few observations

Where are the mental hospitals to obtain "the substantial increase" of staff required by the letter? To secure adequate staff is very difficult, especially in the junior ranks in the provinces Further, in the Metropolitan area some four years ago a situation arose where four hospitals had applied for a registrar yet only two candidates turned up for interview Psychiatry as a specialty lacks the glamour attaching, for instance, to surgery and obstetrics

There is another consideration The D P M is held to be requisite for advancement in the mental health service, and in advertisements for junior posts one reads the famous statement "Every facility will be given for studying for the D P M" On arriving at a mental hospital the junior doctor will find that, if the staff is small, he is required to be on duty two or three days a week and at weekends, which prevents his attending clinical demonstrations at teaching hospitals and a course of systematic lectures It is in fact virtually impossible to hold a full time hospital appointment and at the same time do regular work for the diploma, especially part II

One wonders, however, whether this diploma is as valuable as is claimed In recent years a number of S H M O appointments have been made by regional boards to candidates without it or with part I only Recently I was informed that in a highly psychiatric type of service—the Prison Service—only 4 of the 40–50 doctors possess the diploma

There would, I think, be considerable inducement to enter the mental-hospital service if promotion were to be made automatic What I mean is this After, say, ten years' faithful work in one or more mental hospitals, a junior doctor (registrar or J H M O) could reasonably anticipate being made S H M O This would speed up promotion and would give encouragement to those seeking higher appointments

Dr Strauss's letter raises many very important issues, which deserve urgent consideration

J B GURNEY SMITH

CHRONIC BRONCHITIS AND SMOKING

SIR,—Dr Lennox Johnston (April 27) gives a pungent summary of the extreme arguments against smoking I am personally a life long non-smoker, and privately should enjoy a talk with him Between us, we should agree upon the antisocial outlook of many addicts, but we should differ as to the best method of discouraging the habit Dr Johnston and I are in a minority, and in convincing smokers we shall get further by a more subtle approach His ingenious exercise in psychopathology will not make much impression An Arabian proverb says "It is good to know the truth—but it is better to speak of palm trees"

We have to begin somewhere, and the whole difficulty lies in the fact that, to smokers, smoking is a pleasure This it is absurd to deny, although, like coffee, alcohol, overeating, and other sociabilities, it may also be reprehensible We can hope to be more successful in influencing the young who have never begun to smoke, but anyone who remembers the old fashioned 'temperance" propaganda—based on bottles of hobnail liver—will not care for Dr Lennox Johnston's dogmatism He is a valiant fighter for the truth, but hardly a wise teacher

London, W C 1
HARLEY WILLIAMS

SIR,—In reply to Dr Charles Corfield (May 4), I smoked for 12 years and tried adequately the various methods of smoking and the various kinds of smokes I have no need therefore to ask Sir Winston Churchill or anyone else about smoking and enjoyment Surprisingly, however, Sir Winston's assessment of the enjoyment of smoking was, like my own, negative "If I were to live my life again," he wrote, "I would eschew the habit of smoking"[1] Why he did not do so there and then, I do not know Perhaps its showmanship value, in his exceptional case, counted with him

Wallasey, Cheshire
LENNOX JOHNSTON

SIR,—I read with delight Dr Corfield's letter Thank heavens someone has had the courage to point out in your august columns that smoking is enjoyable And thousands of aged smokers down the centuries can't all be wrong

If I suggest, however, that there is a little more to the gentle art than chain smoking, some may think I have an axe to grind I have And the way it cleaves through some of the less scientific prejudice expressed in your correspondence columns gives me almost as much pleasure as smoking

THE STUDENT AND SEX EDUCATION

SIR,—I am grateful to Professor McLaren and Mr Rossiter (May 4) for their kind remarks on my article in your issue of April 20 While we appear to agree on the need for dealing with this problem, there is a difference in emphasis on the method of approach At Birmingham and several other universities, students are fortunate in having not only enlightened teachers with a broad vision of the larger spiritual aspects, but also the facilities for individual teaching, but the replies to my questionary indicate that these conditions do not exist at certain other universities

Professor McLaren's suggestion of the educational value of a resident 3 months in an obstetric unit is only valid provided that during that time the student is in contact with a teacher who is himself aware of these problems (and especially of their spiritual aspects) and is himself free from inhibition in his teaching and discussion of these problems Some of the replies to my questionary indicate that some teachers are actually antagonistic to any discussion of them whatsoever

I did not mean to suggest that instruction on sex matters should be given only by systematic lectures Rather my suggestion was put forward merely to make the student (and perhaps some of his teachers!) aware of the existence of these problems and so enable them to find, either from books or individuals, the help that they may require In the last analysis it is true, as Mr Rossiter rightly says, that it is personal experience of marriage which is the best teacher Although the number of married students is increasing, their personal experience cannot be a substitute for instruction I should hate, as much as Professor McLaren does, to see this subject becoming a required study for an examination with a special paper But no examinations are required to make students take an interest, for indeed they will cut other lectures to listen to something which penetrates so deeply into the problems of their own lives I can confirm the experience of Dr Sylvia Dawkins at University College Hospital, whose lecture on contraception[2] packed the lecture theatre to the doors When I was invited to give a similar lecture at Manchester University over a year ago, the theatre was crowded with students At many universities the sole lecture given on sex is one by Dr Marie Stopes on contraception, which, in my view, is hardly adequate, contraception is perhaps the least important part of the sex education of the student

The real difficulty facing teaching staffs is to decide who is to give this teaching, and, in some cases, who is to teach the teachers For sex is not the specific province of either gynæcologist, psychiatrist, or minister of religion May not the answer be that an experienced general practitioner should lecture with the support of a panel of gynæcologist, psychiatrist, and minister of religion? The apprenticeship of students to family doctors (as recommended by the College of General Practitioners) would provide excellent opportunities for such teaching, though I am aware of the difficulties in choosing doctors for this purpose Nevertheless, I feel that a few systematic lectures to senior students could provide them with information not otherwise easily obtained and would enable them at least to ask questions of their teachers about problems which, previously, they had not known to exist

COMMON-ROOMS FOR PATIENTS

Sir,—In children's hospitals, it is usual to have play-rooms near the wards, for the use of children not confined to bed Could not the same principle be applied with advantage to adults in general hospitals?

I visualise two types of common-room for this purpose a "quiet" one for elderly people and those recovering from serious illnesses and operations, and an "active" room containing ping-pong table, occupational therapy apparatus, &c, for the less incapacitated

Instead of aimlessly wandering round the hospital in their dressing-gowns, ambulant patients would be able to enjoy the benefits of convalescence while still under hospital supervision

I am sure many readers would be interested to know what is being done about this problem in Great Britain

Cape Town.　**I Mirvish**

HOSPITAL INFECTION

Sir,—As one working in an isolation hospital, I have followed the recent correspondence in your columns with great interest

I must agree with much of what Dr Marsh says in his letter of May 4 As he so aptly states, hospital infection is no new thing After all, it was one of the major causes of death in hospital in the 19th century

Surely its control simply represents the application of common epidemiological principles to special circumstances In this regard the experience gained in the administration of fever hospitals seems to have been forgotten or ignored This is not surprising, resulting as it does from the now commonly held views on hospital administration in general and on the future of fever hospitals in particular

For years before the National Health Service was formed, medical administration in fever hospitals was constantly grappling with the problem of cross infection The principles of barrier nursing and then cubicle nursing were intensively practised in them It was by their rigid application that so many different infections could be treated

I have deliberately used the past tense, because the present day accent on the purely clinical aspects of hospital work has led and will lead to a new generation of doctors and nurses lacking any basic epidemiological training or background Although the contribution of the bacteriologists in hospital and laboratory cannot be ignored, nevertheless much of our existing epidemiological knowledge was built up not by them but by medical officers of health in the field and medical administrators in fever hospitals That both should now be ignored is certainly a sign of the times

If, as seems likely, ultimate official policy is to dispense with fever hospitals as such, then, I submit, the main training ground in hospital epidemiology will be lost Nowadays many of these hospitals face grave nursing shortages It would certainly be to their mutual advantage if all nurses in general training were obliged to do six months training in a fever hospital before their S R N examination, for surely one of the main factors in preventing hospital infection is the nurse with sound epidemiological knowledge

Ilford Isolation Hospital
Chadwell Heath, Essex　**I M Librach**

CLINICAL THERMOMETERS

Sir,—In his letter last week Dr Widlake asks why the so-called half-minute clinical thermometer requires at least two minutes to record a correct reading I have asked this question for fifty years and do not know the answer yet I have not found it in any book which I have consulted A few years ago I was told that the mark "half-minute" was the manufacturers' guarantee that, if the thermometer is placed in warm water about blood heat, it would record the temperature correctly in that time I have asked various of my associates but not one of them has heard this explanation or indeed any other In a letter published two years ago[1] I gave this explanation and asked if it was correct I had hoped that some manufacturer would reply, but none did so Surely it is time that this mystery, which has puzzled the medical and nursing professions for many decades, was cleared up by those who must know the explanation

London W 8　**Henry Tidy**

ATTEMPTS TO PROPAGATE RUBELLA VIRUS IN TISSUE-CULTURE

Sir,—A previous publication[2] reported the appearance of lesions in monkey-kidney tissue-cultures inoculated with rubella throat washings Similar lesions were absent or scarce in control cultures The lesions did not appear in the presence of convalescent human serum

Further passages of both inoculated and control cultures became contaminated with one or more agents derived from kidney tissue or medium[3–5] The passages were discontinued Attempts were made to reproduce the viral lesions in kidney cultures derived from monkeys whose serum contained no neutralising antibody to the contaminating agents To the culture medium was added 2% heated (56°C for 30 minutes) monkey serum containing such antibody No specific lesions appeared and nonspecific lesions were not completely eliminated[6]

Inoculated and control cultures of the latter series were treated with convalescent rubella gamma globulin coupled to fluorescein isocyanate, by a method similar to that of Coons[7] Specific staining of inoculated, but not control, cultures was demonstrated in some experiments, but could not be regularly reproduced[6]

Supernatant from fifth-passage inoculated cultures showing presumed viral lesions was sprayed into the noses of eight human volunteers aged 9 to 27 years, with no history of rubella[3] This material represented a 10^{-10} dilution of original throat washing, the technique of spraying has been described elsewhere[8] After incubation periods of 19, 19, and 20 days respectively three volunteers developed a mild and transient exanthema, low fever (99°–100°F) and slight but definite enlargement of postauricular lymph glands The clinical picture was consistent with a diagnosis of very mild rubella, but was not sufficiently definite to allow a firm diagnosis to be made

Throughout this work there were occasional suggestions that rubella virus was multiplying in monkey-kidney cultures In review, however, we feel the evidence for this propagation was too slender to warrant the conclusion that rubella virus was regularly growing in tissue cultures of monkey-kidney cells The investigation has been discontinued

TARGET CELLS AND SWEAT

SIR,—For the past year or two I have noticed that as the summer approaches, the number of blood-films containing target cells, presented for my inspection, increases On inquiry most were found to be taken from sanatorium patients, as opposed to outpatients and those in the general medical and surgical wards Those particularly affected were the convalescent, who were enjoying the sun If a venepuncture is done at the same time as a finger-prick, the target cells are not present in the films made from venous blood As target cells are readily produced by the addition of a trace of hypertonic solution to the blood, I suspect that the finger-prick pierces an actively secreting sweat gland This seems to be at least one explanation of this well recognised artefact

Braintree, Essex

A I D PRENTICE

TREATMENT OF A DIABETIC DOG

SIR,—I wonder whether some of your readers would be interested to know of the successful management of diabetes mellitus in a dog

The dog, Teddy, aged 9 years and weighing 29½ lb, developed severe thirst and polyuria three and a half months ago He was overweight, and had been so since he was neutered some years previously He was sleeping a great deal, he had an anxious expression, and his gait was rather hesitant Urine examinations revealed heavy glycosuria

A veterinary colleague was consulted and, as a short course of dieting made no impression on the symptoms or glycosuria, insulin treatment was begun

The disease must have been in its early stages For the first month it was easily controlled with a morning injection of protamine zinc insulin of 10 or 12 units For the next two months the diabetes relentlessly progressed in intensity Although the dose of insulin was increased almost daily, and eventually soluble insulin was added to the protamine zinc, it seemed impossible to control the disease

Just over two weeks ago, however, the diabetes became stabilised on 100 units of insulin (52 units soluble plus 48 units protamine zinc) given as a single morning injection The urine is clear, but ¼–½% "sugar" appears in the urine if the dose of insulin is lowered to 96 units

Fortunately a young member of my family is an expert at collecting specimens He, Teddy, and a bowl adjourn down the garden, once or twice a day, to a convenient tree and soon return equipped to carry out a 'Clinitest'

The dog has two meals a day of meat and biscuits He has maintained his weight and is now very alert and lively At no time has there been any tendency to hypoglycæmia Night vision may be slightly impaired

Teddy fortunately does not resent the injections, which are given through the loose skin on the neck or along the back He has developed a conditioned reflex, realising that the injection is followed by his breakfast, and on some days I find him waiting for me outside the surgery door

Our veterinary friend has been unable to find any clinical evidence of pituitary or adrenal disease, and pancreatic function seems to be otherwise normal

As the original experimental work on insulin was carried out on dogs, I felt it would be pleasant to record a severe case of diabetes in a dog which has benefited from that work

Thames Ditton Surrey

C HOWICK SMITH

ÆTIOLOGY OF PRE-ECLAMPSIA

SIR,—Mr Theobald (March 30) challenges the connection between bilateral cortical necrosis and toxæmia and questions my view that uterine tension is concerned in pre eclampsia Regarding the former, although the supervention of cortical necrosis on toxæmia is rare, the connection does exist as I will show

Experimentally, moderate cortical ischæmia can be produced by the resistance to stretch of the rabbit's uterus[1] Similar moderate ischæmic changes follow moderate stimulation of the renal nerves while the most severe stimulation of these leads to the severest degrees of renal shutdown In the milder ischæmia, as a result of such stimulation there is an exudate into Bowman's capsule similar to that revealed by renal biopsy in pre eclampsia while in the most severe ischæmia thus provoked all the changes of cortical necrosis are reproduced Nephron dissections separate the renal damage into the purely ischæmic and the ischæmic plus toxic They have shown that in the rare cases of eclampsia ending in fatal anuria, and in anuric concealed accidental hæmorrhage, the histological findings are indistinguishable In *both*, nephron dissection reveals only an ischæmic lesion—a fact also significant in excluding a toxin from the ætiology It seems therefore that in cortical necrosis the changes are the severest seen in states of cortical ischæmia, and that pre eclampsia per se is a much milder stage Clinically the dramatic manifestation of severe cortical ischæmia is anuria—a condition always due to marked renal shutdown

The connection between anuria thus appreciated and eclampsia is further revealed by the effects of administration of hypertonic saline to the anuric who as a result develops œdema, hypertension, and fits—the typical pre eclamptic/eclamptic state[2], while further, if the sequence is reversed and the experimental animal is rendered anuric by renin after salt and water retention had been potentiated by previous deoxycortone[3] and salt administration, œdema, hypertension, and fits result also Both the foregoing reveal the close though occult relationship of an acutely shutdown kidney with the eclamptic process when salt and water retention is an accompaniment

That the uterorenal reflex is essentially responsible for the anuria of concealed accidental hæmorrhage is evident from the extreme stretch resistance of the myometrium, and the clinical improvement after rupture of the membranes and splanchnic block The presence of a lesser degree of shutdown in pre eclampsia is indicated by the histological findings of renal biopsy, by the clinical signs (all of which *can* be entirely due to cortical ischæmia), by the reduced glomerular filtration rate,[4] and by the benefit conferred by measures which reduce renal resistance (e g, spinal anæsthesia, hydrallazine)

Obstetric anuria is thus an acute and severe shutdown, without previous accumulation of salt and water, unless pre eclampsia precedes it Pre eclampsia, on the other hand, is a less severe, gradual, and continuing ischæmia not attaining a complete shutdown usually, leading to salt and water accumulation and to consequent toxæmic manifestations

Mr Morris (April 13) has doubts about the relationship of myometrial *tension to pre eclampsia* In pregnancies complicated by hydramnios and twins, there is a greater likelihood of toxæmia, and in concealed accidental hæmorrhage the retention of blood can also provoke toxæmia In all these conditions intra uterine pressure is increased, but, apart from this obvious change, there is a more important association emphasised by the ætiological significance of primiparity in toxæmia—and that is the change in tension evoked. The explanation lies in the formula

[1] McGaughey H S Weller H Parker Anslow W *Amer J Obstet Gynec* 1956 72 589

[2] Dieckmann, W J Toxemia of Pregnancy St Louis 1952 p 447

[3] Renzi A A Gaunt R *Ciba Symp* 1954, 6 1 30

[4] Page, E W *Gestation* Transactions of the 3rd Conference Josiah Macy Jun Foundation New York 1956 p 83

$$\text{Tension} = \frac{\text{pressure} \times \text{radius}}{2}$$

Increase in tension is the basic cause of toxæmia. As Reynolds[5] has pointed out, the radius of curvature of the primigravid uterus—invariably cylindrical after mid-term—is much greater than that of the usually globular multigravid uterus. Moreover, the contractions of labour can aggravate toxæmia, again reflecting the harm done by increased tension; while sustained contractions, with their tensioning effect, can initiate toxæmia as Nixon has shown.

Experimentally, increased tension is manifest in reduction of the myometrial circulation, as demonstrated in toxæmia by Mr Morris and his colleagues and others. Mr Morris found in one case that toxæmia lessened after fœtal death and the myometrial circulation improved though the fœtus had been retained. Here, tension may have become less because of the reduced tone of the dead fœtus and the withdrawal of hormonal stimuli to the myometrium. Corner and Csapo have shown that œstrogen increases the isometric tension of the uterus, which depends on the actomyosin content of the muscle. Adenosine, an actomyosin derivative, is much increased in toxæmia, for Green has found this increase of circulating adenosine in toxæmia ascribable to ischæmia of the uterine muscle and reflecting its increased tensions as well.

Clinically, Parviainen and his colleagues have shown that uterine tone is increased in nearly every case of severe toxæmia. Others have found an increase in blood pressure accompanying heightened uterine tonus.

Pre-eclampsia and acute glomerulonephritis are clinically very similar—œdema, hypertension, albuminuria, and maybe fits. Renal biopsy confirms the reversibility of the changes in both conditions and shows the similarity of the exudate in Bowman's capsule and the bloodlessness of the glomerulus. Both in pre-eclampsia and acute glomerulonephritis, the glomerular filtration rate is reduced. A significant recent finding is that salt induces hypertension at certain stages of acute glomerulonephritis[6]; this corresponds closely to the effect noted in toxæmia by Dieckmann—an effect that could be based on an accompanying renal ischæmia.

Apart from the confusion between tension and pressure, to which Dr Smyth (May 4) has referred, another explanation for the apparent exceptions to the tension-ischæmic link is the variable response of the kidney (e.g., the different incidence of recovery from nephritis after scarlet fever, the higher incidence of hypertension in older pregnant women, and the variable effect of posture and rest). Mr Morris's contention that serotonin can be held responsible for the cortical necrosis of concealed accidental hæmorrhage can be completely refuted by the fact that this hormone is responsible for characteristic symptomatology (especially severe dyspnœa) in argentaffinoma—symptoms never encountered in obstetric anuria; while his difficulty in accepting the Hæmex reaction as an explanation of the renal reflex postulated would be entirely removed by a realisation that the effector materials in question act as stimuli only while they are in the fresh state.

I agree with Dr Schuurmans (April 20) that the adrenals are concerned in hypertension in pregnancy, but as I argued at the meeting of the Royal Society of Medicine on Feb. 22, the corticoids (or any other hormones)[7] are not the primary cause. I cannot now deploy these arguments again, but one further fact may be added: cortisone-induced hypertension is maintained in spite of sodium deprivation and therefore cortisone cannot be responsible for the hypertension of toxæmia, which can often be reduced by restricting salt intake.

A sound knowledge of the problems involved emphasises the futility of a demand for direct measurements of these ætiological factors, while awareness of the fixity of the fœtal head and the difficulty of version in the primipara equally emphasise heightened tension.

London, W 1 JOHN SOPHIAN

SERUM-CYANOCOBALAMIN LEVEL IN CHRONIC INTESTINAL DISORDERS

SIR,—I have read with interest the article by Dr Meynell and his co-workers (May 4) on this subject, but am not as surprised as they are at the incidence of cyanocobalamin deficiency that they have found in idiopathic steatorrhœa. I am quoted in their excellent article as having found only 1 patient with a low serum-cyanocobalamin level among 29 with intestinal malabsorption of the sprue type. This statement is, however, misleading, as reference to table I of my paper,[1] will show. This table was concerned in particular with an investigation into folic-acid absorption; in fact, the serum-cyanocobalamin levels were given for only 17 patients, 6 of whom did not have megaloblastic anæmia. With 1 exception, no attempt was made to measure the serum-cyanocobalamin levels of patients who had been treated with cyanocobalamin or liver injections, and no doubt several of these had had low serum-cyanocobalamin levels before such therapy was given. At present we are investigating some of these patients by measurement of the absorption of labelled cyanocobalamin, and there is, as expected, evidence, in some, of malabsorption not only of folic acid but also of cyanocobalamin.

University of Edinburgh. R H GIRDWOOD

EFFECTS OF ASCORBIC ACID ON THE HEART

SIR,—The oxidation/reduction processes play a very important, and possibly a decisive, rôle in the origin of electric potentials in living tissues. According to many authors, at least one phase of the action current depends on these processes. We are investigating the effects of ascorbic acid on the course of the action currents in the frog's heart, isolated and in situ.

In the first series of experiments we exposed the heart to a concentration of 1 in 10 ascorbic acid. Almost immediately there was a big increase in electric potential in the fading-out phase of the action current, which showed itself as an increase in the height of the T wave of the electrocardiogram (E C G).

In the second series of experiments we produced a low S T segment and inversion of the T wave by the use of strophanthin K. If the heart was then exposed to a 1 in 10 solution of the sodium salt of ascorbic acid, these effects were reversed: the S T segment became isoelectric, and the T wave positive.

With the heart in situ the same effects were seen, but they proceeded more slowly. No similar effects were seen in control experiments using other acids.

Ascorbic acid was used because it is readily available and not toxic. We explain the lack of effect on the E C G of ascorbic acid in the usual doses by the fact that it is altered in the pulmonary circulation and reaches the coronary arteries in an inactive form.

It might be possible to use ascorbic acid clinically in massive doses (e g , 10 g daily intravenously) to prevent the electrocardiographic changes typical of digitalis. Ascorbic acid might be protective in cases where digitalis is indicated in the presence of coronary insufficiency. In emergencies a massive intra-arterial dose could be given.

Parliament

The Bomb Tests

In the debate on defence policy in the House of Lords on May 8, Lord **Cherwell** (formerly Prof F A Lindemann) stoutly defended the Government's intention to test nuclear weapons in the Pacific, and he discounted the risks to health of such tests as "negligible, not to say non-existent"

The British tests, he said, could not in any circumstances cause any significant increase in the number of stillbirths or defective children or of cases of leukæmia or bone cancer The question had been investigated by the highest authorities, who had agreed that the risks were negligible But people tended to believe the views of much less knowledgeable men, whose assertions were widely circulated as though they were the last word It was quite a joke now in scientific circles that if anyone wished to be advertised in the newspapers as a great nuclear expert, he had only to say that the British tests should be stopped Lord Cherwell was shocked to see that The Lancet had seen fit to countenance this campaign and had supported the views of "some unofficial group" which contradicted flatly the conclusions of the Medical Research Council committee It was amazing that such a journal should have so little regard for the leaders of the profession Among other cardinal errors, Lord Cherwell continued, the conclusions countenanced by The Lancet were based on the assertion that 0 1 microcurie of radium would cause 1 man in 200 to get bone cancer According to the International Commission on Radiological Protection, this quantity was permissible, and "permissible" was defined as "not expected to cause appreciable bodily injury to a person at any time during his lifetime"

It was very undesirable, Lord Cherwell declared, that such tendentious views, clearly based on wishful thinking, directly at variance with the conclusions of the most distinguished men who formed the International Commission, should be promulgated as though they were authoritative This sort of thing became particularly obnoxious when universally respected figures like the Pope and Dr Schweitzer were persuaded to intervene

The gamma radiation to which we were exposed from the fission products of all tests up to date was 150 times weaker than natural background radiation To frighten people by making out that this slight increase, two-thirds of 1%, was going to increase the mutation-rate by an appreciable fraction was deliberately dishonest Even the most cautious experts agreed that the effect of adding an extra 100% or 200% to the natural background dose would be negligible Yet 0 6%, according to our vociferous cranks, meant danger to the human race

Strontium 90 seemed to frighten people just because it had been linked with the hated word "cancer" According to the Medical Research Council's investigation, the amount of strontium 90 which we had absorbed up to date was 1000 times less than the amount considered safe for people working in factories where radioactive materials were used "Even if we allow a factor 10," Lord Cherwell remarked, "in case infants absorb more strontium than adults, we still have in hand a safety factor of 100"

No-one could be sure what would happen with radiation of such low intensity, but, Lord Cherwell added, "if anyone were to tell you that because half the people who took one grain of some poison died it followed that taking one six-hundredth of a grain would kill 1 person in 1200, I think you would be rather surprised I am not saying it is quite impossible in radioactive things, but it seems unusual"

Only those who had detailed knowledge of the design of the British bombs and knew how much strontium was produced in the detonator or blanket could form any idea of the amount the Christmas Island test would add to the atmosphere It was montrous that, lacking this essential datum, anyone should allow the assertion to appear in the press that the débris of every megaton equivalent would kill a thousand people

Referring again to those who opposed the continuation of nuclear tests, Lord Cherwell said "these well-meaning dupes forget that even if the tests did add to some tiny extent to the number of people who suffer from bone cancer or to the number of stillbirths, this would be a small price to pay for developing a really effective deterrent which would prevent war" It was moonshine to insist that radiation from débris of nuclear tests would cause adverse genetic effects, and, as for strontium 90 in bone, even the most pessimistic assumptions had only been able to make out that this amounted to a hundredth or even less of the quantity which the International Commission had declared safe for industrial workers These questions were plain scientific matters of fact There was no party issue involved at any rate there ought not to be

*** This debate is discussed in an editorial on p 1029

The National Health Service Contribution

On May 8 Mr **Dennis Vosper**, the Minister of Health, introduced the second reading of the Bill which increases the direct contribution from all insured people towards the National Health Service It also gives the health service contribution a separate existence and ends its administrative symbiosis with the National Insurance contribution Though, for reasons of convenience and economy, the health service contribution will continue to be collected under the shelter of the National Insurance stamp, its independence will be recognised by overprinting on the stamp the words "includes (rate) health service" Mr Vosper promised that when a new stamp is introduced the words would be incorporated in the design

Most of the points raised in the debate had been mentioned in what was described as the "preliminary canter" on the ways-and-means resolution[1] The Opposition regarded the increased charge as a regressive poll-tax and feared that the Government intended that contributions should play an ever larger part in financing the service The Government denied that it was their intention to shift the whole burden of the cost to either contributions or charges, but they wished to restore the balance between contributions and taxes which held when the service was started

Behind the financial cross-talk it was clear that speakers on both sides of the House felt that the National Health Service, though admittedly expensive, was a valuable national asset Several speakers made it plain that if people were asked to pay this extra contribution they should be sure of getting value for their money The preventive and industrial services, and hospital buildings, were given as examples of parts of the service on which more money could profitably be spent It was also clear that there was some uneasiness about the prescription charges Many people would be reconciled *to even larger contributions by the discontinuance of this charge on the sick*

Extension of Domiciliary Services for *Old People*

On May 10 Mr **Ronald Williams** moved the second reading of a private member's Bill which seeks to amend the National Assistance Act, 1948, so as to empower local authorities to make their own arrangements for domiciliary services for old people At present local authorities may only contribute to the funds of voluntary organisations which offer these services to old people Mr Williams *emphasised that it was not intended that the* Bill should in any way prejudice voluntary work, but there were many areas where old people were living in distressing circumstances and no voluntary organisations existed

Mr **Vosper**, the Minister of Health, said that this work seemed particularly suitable for voluntary organisations, and if the Bill received the assent of the House he hoped that wherever possible a local authority would use a local voluntary organisation as its agent He reminded Members that several local authorities had already, by private Bills, obtained powers of this kind The present Bill, he pointed *out*, empowered local authorities other than county and county-borough councils to provide these services and seemed to envisage the employment by the smaller authorities of visitors to render them About this he admitted that he was uneasy, for he feared that it might lead to fragmentation At present domiciliary workers were employed only by county and county-borough councils and he felt that the domiciliary health and welfare services should be kept together as a team He also thought it would be wiser to await the completion of the review of local government and its finance Apart from these reservations the Government was in favour of the Bill in principle and would not oppose it, but would seek to improve it in committee

---

The Bill was given a second reading

Visits to Mental-hospital Patients

On May 10 on the adjournment Mr **NORMAN DODDS** suggested that the attitude of the Ministry of Health to his requests to visit a patient in a mental hospital "revealed a disturbing state of affairs suggesting a deterioration in the safeguards affecting the liberty of the individual under our mental laws" His request, he related, had been referred to the medical superintendent of the hospital with whom, he was told, the final decision rested This he submitted was in fact not so, and he quoted regulations to show that the final authority was the Board of Control Why, he asked, had he not been informed that the board had an interest in the matter? He suggested that the board had ceased to be the instrument that it was set up to be—the safeguard of the liberty of the individual Not only had the board moved into the Ministry of Health building but its members held appointments on the staff of the Ministry

Mr **J K VAUGHAN-MORGAN**, parliamentary secretary to the Ministry, replied that the Board of Control still retained the duties originally held by the Board of Control and by the Commissioners in Lunacy in respect of the liberty of the subject The board was an independent body constituted by the Mental Deficiency Act, 1913 It was reorganised in 1930, and in 1948 certain functions were taken from it, but it retained the residual duties that it previously had Apart from the power to make statutory regulations and the power to direct the chairman as to the arrangements for the administrative business of the board, there was no statutory provision whatever which gave the Minister power in any way to control the board in the performance of its duties

Turning to the relationship of the Minister to the medical superintendent, he said that the superintendent was employed by the regional hospital board Under the terms of the National Health Service Act the Minister could indirectly, via the board, issue a direction to him on any subject, but whatever the legal position might be, no Minister would for a moment consider directing a medical superintendent on any matter such as this when that medical superintendent was primarily responsible for the health and welfare of a patient A visit to a patient detained in a mental-deficiency hospital might be paid at such times as the superintendent might direct If the superintendent did not direct, no visit could be paid The Board of Control could override the medical superintendent about visits to a patient, but the Minister could not direct or overrule the Board of Control

QUESTION TIME

Nuclear Tests

Dr **BARNETT STROSS** asked the Prime Minister whether he was aware that no threshold dose for radiostrontium might exist and that tests of nuclear weapons might already be responsible for some 50,000 cases of bone tumour in the future, and if he would therefore postpone the proposed British tests in the Pacific —Mr **R A BUTLER**, the Home Secretary and Lord Privy Seal, replied I assume that the hon Member has in mind statements in a report published by the Atomic Scientists' Association. I would draw his attention to the careful reservations made by the authors, they state

> In giving these estimates it must be emphasised again that apart from the considerable margin of error due to lack of adequate data they are based on the as yet unproved hypothesis of a proportional relationship applying to very small doses From this point of view they represent the most pessimistic approach

I am informed that the estimates made in this report are interpretations of factual evidence which was available last year to the Medical Research Council's special committee, but that the latter did not consider it an adequate basis to justify their making such calculations In these circumstances, the Government are not prepared to postpone the proposed tests

Dr **STROSS** Whilst accepting the quotations, may I ask whether the Minister does not agree that, although no one dare be dogmatic about this rather, terrifying risk that we are discussing and there is some doubt, any benefit of the doubt must be given to posterity, and that we have no right to be euphemistic or optimistic about this matter and the only possible way of approach is by pessimism and not by optimism?—Mr **BUTLER** I have in mind that the data available was before the M R C's special committee a year ago and we had it in mind at that time Therefore, I am not prepared on behalf of the Government to make an answer, on behalf of the Prime Minister, saying that we would abandon the tests on the basis of the atomic scientists' report which comes a year later I am prepared to take the matter most seriously, but I am not prepared to give any further conclusion

Mr **HUGH GAITSKELL** In view of the length of time which has elapsed since the M R C's report, the number of statements made by scientists in various countries, and the amount of additional evidence made available, could the Minister ask the M R C for a further report to bring the matter up to date?—Mr **BUTLER** I am certainly ready to do this, but I must honestly say that, since the M R C's report was published, no relevant new fact has become available as far as we are aware. Some fresh estimates have been made of the rate of accumulation of radiostrontium in human bone, but according to the information in my possession it would not be worth while doing what the right hon Gentleman suggests I will, however, certainly consider the suggestion and discuss it with my right hon Friend

Mr **N W HAMILTON** Will the Minister, in view of the conflicting views of world scientists on the harmful effects of nuclear bomb explosions, initiate the calling of an international conference of scientists in order to ascertain at least the minimum area of agreement?—Mr **BUTLER** The United Nations set up, in 1955, a Scientific Committee on the Effects of Atomic Radiation The committee, consisting of most respectable representatives of the most respectable nations, last met in Geneva from April 8 to 19 The whole question of radiation hazards and the effects of strontium 90 was considered by the committee, which is still collecting information, on which it will take some time to reach conclusions As this is an international body of scientists I should prefer to give it an opportunity to reach conclusions before we do anything else

Mr **GEORGE THOMAS** In view of the disturbing statement made yesterday by the Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries, and Food about the rate of strontium radiation found in the Welsh mountains and in that district[1] is not the Minister prepared to recognise that this is a new factor? How long have the Government had information about this, and will they continue to increase the amount of radiostrontium on these hills thereby risking the well being of future generations?—Mr **BUTLER** Those of us who have responsibility in these matters realise that strontium on herbage, especially on elevations such as the Welsh mountains, is the most easy to calculate But there is nothing I can *add at present to the reply* given by my right hon Friend the Prime Minister that so far the present averages measured in the United Kingdom are 67 of a unit for children under five years of age and much less for the rest of the population The International Commission on Radiological Protection accepted 1000 units as a maximum allowable for workers in special occupations Therefore, so far, although it is a matter of concern that on herbage on elevations especially in the Welsh mountains, there should be this deposit, we do not think the matter has reached a stage about which we need be unduly alarmed

Mr **ANEURIN BEVAN** Is it not extraordinary, when there is not doubt about the fact that these poisons are being spread throughout the atmosphere and that they are irreversible, that we should proceed to these tests before we get the report from the international body of scientists? If the extent of the poisoning is unknown but the fact that it is occurring is known, would it not be more civilised to stop all tests until we have the report?—Mr **BUTLER** The right hon Gentleman is ignoring the march of science It may be that through the process of tests we may find that the radiation effect is less marked than it is thought to be at present It is certainly not the intention of the Government, for reasons of scientific appraisal and for reasons of the defence of the country, to abandon the tests at the present time Mr **BEVAN** As far as we understand, there is no doubt about the fact that poisoning is taking place There is no doubt either that the poisoning is irreversible What there is doubt about at the moment is its extent Would it not, therefore, seem to be reasonable to everybody in all parties that until the facts are established by the international body of scientists, no more poisoning should be permitted ?—Mr BUTLER No, Sir I have said that for two reasons, namely, the scientific and the question of national defence, we think the tests should proceed in the interests of all

---

[1] See *Lancet*, May 11, 1957 p 990

Mr GAITSKELL Can the Minister seriously argue that a postponement of these tests until the report is available would seriously endanger our national defence, or, indeed, interfere with the march of science ?—Mr BUTLER I am following, with I think absolute justice, the line which the Prime Minister has followed, and I think rightly followed, for the two reasons I have given—namely, in the forward march of science tests are necessary, they are also necessary in the interests of national defence

Day Hospitals

Day hospitals for the treatment of mental and nervous illness exist under the following regional hospital boards and boards of governors

Leeds
  St James' Hospital, Leeds
  Scalebor Park Hospital Burley in Wharfedale
  De la Pole Hospital, Hull
Sheffield
  Drury House, Leicester Road Narborough, Leicestershire
North West Metropolitan
  38, Marlborough Place, St John's Wood, London N W 8
North East Metropolitan
  Goodmayes Hospital, Goodmayes, Essex
South East Metropolitan
  38, Mason's Hill, Bromley Kent
South Western
  12, Grove Road, Redland Bristol, 6
Wales
  Whitchurch Hospital, Cardiff
Birmingham
  Uffculme Clinic Queensbridge Road, Birmingham 13
  All Saints' Hospital, Winson Green Birmingham 18

  Oldham and District General Hospital Oldham
  Westhulme Hospital Oldham
  Cowley Road Hospital, Oxford
Bethlem Royal and Maudsley
  Bethlem Royal Hospital Beckenham
  Maudsley Hospital, London S E 5

Arsenic in Foods

Statutory limits for arsenic in foods are to be laid down and regulations will be introduced as soon as practicable based on the Food Standards Committee's recommendations of Jan 31, 1955 Full details of the proposed regulations will be circulated for consideration by the interests concerned

Public Health

POLIOMYELITIS VACCINATION

THE Ministry of Health has informed local health authorities that poliomyelitis vaccine will be distributed throughout the summer, although it will be left to medical officers of health, in the light of local conditions, to decide whether to continue or suspend vaccinations in their area It will be remembered that last year vaccination was suspended at the end of June That decision was taken because of the possible danger that vaccination during an outbreak might provoke poliomyelitis Since then the Minister of Health has sought the advice of the Joint Committee on Poliomyelitis Vaccination, which in turn asked for information from public-health services in countries which have had considerable experience with poliomyelitis vaccine, including the U S A and Australia No evidence has been obtained from these sources that poliomyelitis vaccination can provoke paralytic disease Paralytic poliomyelitis following inoculation has been associated particularly with alum-precipitated diphtheria toxoid and combined diphtheria-pertussis inoculation, whereas pertussis vaccine alone has not been associated with inoculation poliomyelitis in this country [1] Poliomyelitis vaccine seems to be similar to pertussis vaccine in this respect, and the committee felt that in general vaccination against poliomyelitis need not be suspended when the disease is prevalent

It has also been announced that the next groups to be offered poliomyelitis vaccine will be children born in 1955 and 1956 Afterwards children born in the years 1947–54 who were not previously registered will be offered another opportunity Parents will be asked to express in writing their wish to have their children vaccinated, and they are advised to watch for announcements from their local medical officer of health As before, two doses of vaccine will be given Until the end of April, sufficient vaccine for three quarters of a million children had been released The vaccine has been produced by one firm, but it is hoped that a second firm will soon come into production Suggestions have appeared in the press that extra vaccine should be imported from the U S A, but one difficulty about this is that British vaccine has been made with a less virulent strain of type 1 virus than that which is used in American vaccine, and it is argued that this change of strain has been an important factor in the safety of British poliomyelitis vaccine

---

MEAT HYGIENE

A W H O monograph [1] brings together the latest information about the safe processing of meat from producer to consumer, emphasising that there is no room for complacency over meat hygiene either in under developed or in advanced countries No country can afford the disruption of activities in the home, or in the population generally, due to meat-borne diseases Meat hygiene also has an important economic rôle in averting losses in meat or its by-products and in preventing diseases which are transmissible to other domestic animals

In part I, C E Dolman considers the zoonoses, including the less well known ones such as pasteurellosis, leptospirosis, and listerellosis Not everyone may agree with his suggestion that in some parts of the world meat-inspection regulations and procedures respecting tuberculous cattle are probably too lenient This matter is reviewed exhaustively by H Drieux in the monograph

The section on slaughter includes many useful data In Britain all animals intended for human food must be stunned by means of a mechanically operated instrument, except animals slaughtered ritually for consumption by Mohammedans or Jews The admissibility on humane grounds of these ritual methods of slaughter has concerned health authorities and welfare societies for many years, and it is perhaps regrettable that the experts concerned with this monograph did not pronounce on this important subject A brief reference is made to a new method of pig stunning by inhalation of carbon dioxide gas—a method now being used in large abattoirs in the U S A and Scandinavia

Part IV deals with post mortem inspection H Thornton describes the general principles for this inspection and the judgment of diseased carcases and discusses the code of judgment in Britain, known as Memo 3/Meat Elsewhere the question is discussed whether codes of judgment should be discretionary or statutory, prescribing the form the post mortem examination should take and the judgments to be applied when the carcase or organs are abnormal or diseased Attention is drawn to the inspection problems presented by animals which are *slaughtered in emergency*, and to the value of bacteriology in judging fitness of such carcases for food

The techniques of bacteriological examinations and biochemical tests are dealt with by A Jepsen, who provides indisputable evidence that the extensive use of these tests brings greater accuracy to judgment, and is the means of saving much meat which would otherwise be condemned The monograph recommends that any slaughterhouse of importance should have its own laboratory where bacteriological and biochemical tests can be applied in any suspected case

---

[1] Meat Hygiene World Health Organisation monograph series no 33 H M Stationery Office P O Box no 569 London S E 1 Pp 527 30s

In a section on the judgment of carcases affected with tuberculosis attention is drawn to the importance of recognising the nature of the lesions, for this indicates whether the disease is quiescent or whether it is active and likely to be disseminating bacilli throughout the systemic circulation Although meat as well as milk can cause tuberculosis in man, it is now clear that the possibility of infection through the digestive tract from meat carefully freed of tuberculous lesions is extremely small

---

Obituary

WILLIAM HOWARD TYTLER

B A , M B Toronto

Dr W H Tytler, formerly professor of tuberculosis in the Welsh National School of Medicine at Cardiff, died on May 6 at Banchory, Kincardineshire, at the age of 71

He was born at Guelph, Ontario, and the first part of his life was spent in Canada and the United States After graduating M B from the University of Toronto in 1909 he held hospital posts in Montreal and Hamilton and later became assistant pathologist to the New York Hospital In the 1914–18 war he served in the Canadian Army Medical Corps in France and Belgium When he was demobilised he came to this country to work with the Medical Research Council at Hampstead During the three years he spent on the staff of the council he visited West Africa with the first Yellow Fever Commission

In 1922 Dr Tytler began his work in Wales when he was appointed bacteriologist to the central tuberculosis laboratory of the Welsh National Memorial Association at Cardiff, and he held this post until 1938 when he became professor of tuberculosis in the Welsh National School of Medicine He resigned from the chair in 1949 to become consultant adviser on tuberculosis laboratories to the World Health Organisation, and in this post he travelled extensively in Europe, India, and the Far East He retired in 1952 to take up poultry-farming in Scotland A keen gardener, he applied scientific knowledge to producing vegetables easily

S H G writes

Bill Tytler was shy and retiring, but once one was accepted as a friend he became a most charming and entertaining colleague His modesty overcome, he would tell of his experiences with Noguchi and others, and it was easy to realise the width of his knowledge and that his interests were both national and international He was of a restless inquiring nature and he had an able brain, trained to be precise and logical Undergraduate teaching was irksome to him and students sometimes had difficulty in following his trend of thought, but he was always in his element when discussing with postgraduates some abstruse problem in tuberculosis He was essentially a bacteriologist and never professed to be a clinician His publications were few but of outstanding quality, and his memorandum on B C G vaccination prepared in 1944 did much to influence those in authority to introduce its use to this country in 1949

All those who knew him well have derived much good from his companionship

In 1945 he married Miss Eileen Sellar, who survives him

BERNARD EHRENFRIED MYERS

C M G , M D Edin , F R C P

Dr Bernard Myers, consulting physician to the Royal Waterloo Hospital for Children and Women died at his home in London on May 9 at the age of 85

He was born at Auckland, and he was educated in New Zealand at Wellington College He came to this country to study medicine and he graduated M B in 1898 from the University of Edinburgh After holding a demonstratorship of anatomy there he took his M D with commendation in 1900 Afterwards he turned more and more to work among women and children He held clinical clerkships at the Coombe Hospital in Dublin and at the Hospital for Sick Children, Great Ormond Street, and the Royal Waterloo Hospital in London He began to write papers and booklets on child care, home nursing, and infant feeding and in 1910 he set out his plan for a model crêche About this time he joined the staffs of the Western General Dispensary and the Royal Waterloo Hospital

Dr Myers always maintained close ties with New Zealand, during the 1914–18 war he served as acting director of medical services to the New Zealand Expeditionary Force, and in 1917 he was appointed C M G in recognition of this work After the war he returned to his consulting practice in London His book on *Diseases of Children* appeared in 1922 and that on *Modern Infant Feeding* in 1930 In 1933 he was elected F R C P , and in 1937 he gave the unexpended balance of the funds of the St Marylebone Children's Clinic to the college to institute the Charles West lecture on the diseases of children Dr Myers was a past-president of the West London Medico-Chirurgical Society For many years he was consulting physician to the New Zealand government in London and commissioner in the United Kingdom for the New Zealand Red Cross

G S writes

A room in a dispensary off the Edgware Road in the 'twenties—an atmosphere of smells and cries inseparable from a children's department, white coated voluntary nurses weighing and measuring infants, and supervising it all, with courtesy, geniality, and obvious love, a gentle, rather stage type doctor This is my first memory of Bernard Myers As the years passed, these memories were strengthened At the Royal Waterloo Hospital, where I was his colleague for many years, he was for long the pædiatrician and will be remembered for his kindness and his skill with his small patients Highly regarded by all of us, he was a man of intense loyalty and could be relied on in any controversy—for there were controversies even in those days

His interests were varied He was proud to have been elected president of the West London Medical Society, and, working with him there too, I know how much time and thought he gave to the society His genial chairmanship of the annual dinner will long be remembered He was equally popular at the Savage Club and at the Waterloo Hospital dining club

In his passing at a ripe age I think that courtesy and kindness and a love for all humanity, especially children, are my outstanding recollections There have been more famous pædiatricians but never a greater gentleman

Dr Myers's wife died in 1953 He is survived by their three daughters

WALTER LIDWELL HARNETT

C I E , M A M D Camb , F R C S

When in 1934 Colonel Harnett retired from the Indian Medical Service after almost 30 years of distinguished service as a surgeon and teacher, he lost no time in embarking on a fresh career, and his thirteen years' work as medical secretary of the clinical cancer research committee of the British Empire Cancer Campaign were spent in compiling the monumental *Survey of Cancer in London* which appeared in 1952

He was born in 1879, the son of Dr W J Harnett F R C P E , of Barnet From the City of London School he went with an exhibition to St John's College, Cambridge, and after taking a first in the natural sciences tripos in 1899 he continued his medical studies at St Thomas's Hospital, where he held a university scholarship He qualified in 1903 and took the F R C S the following year He was a house-surgeon and assistant pathologist at St Thomas's before passing into the Indian Medical Service in 1907 The same year he won the Montefiore prize at the Royal Army Medical College After four years' military duty he was sent in 1911 as civil surgeon to Gauhati in Assam In 1914 he was posted to Bengal as resident surgeon at Calcutta Medical College During the 1914–18 war he was recalled to military duties and he served on the North-West Frontier, at Salonika, and, after the armistice, in Constantinople In 1925 he was appointed superintendent of the Campbell Medical School in Calcutta and he was also surgeon to the governor of Bengal For the four years before he retired in 1934 he was professor of surgery at the Medical College of Calcutta, and his quality as a teacher and his pioneer work in orthopædics were recognised when he was appointed C I E in 1933

Soon after his return to this country he began his work with the British Empire Cancer Campaign, and of his new career S C writes

It seems but yesterday since Harnett retired from his main job in life, "being a surgeon in India," and yet it is about 20 years Since his so called retirement he carved for himself a second career and in this period acquired many friends I only knew him in this second phase, and learned to appreciate his mixture of gentleness and determination, his politeness, his accuracy of thought, his desire to serve the British Empire Cancer Campaign, and his frustrations with his material Imagine this man, so punctilious in his pursuit of accuracy, faced with follow-up cards filled in by busy, harassed, temporary registrars at "a bob a card" Imagine this in war time, when cards relating to the civilian cancer patient were remote from the main interest of most doctors Yet with these slender twigs of death records, he built a monument, *The Survey of Cancer in London* Whatever the value of this statistical review—and all such studies are of transient interest only—it gave him a background for his intellectual life He got acquainted with the younger generation of hospital doctors in Greater London, he visited them, even pursued them at times, he discussed his work with them and then quietly saw the older generation and tried to balance the views

I cannot speak of him as a colonel or an operating surgeon, only as a retired colonel, a paper surgeon, yet in the 20 years I knew him, I got to like him more and more, and to respect his character If in the Valhalla he just joined there are record cards, I feel sure he could not resist taking them for scrutiny to Lockhart-Mummery, and saying what he so often said to me "you think this is true?" If the pursuit of truth is an achievement in itself, Harnett has achieved his ideal His memory will long linger with all who knew him

Colonel Harnett leaves a widow, formerly Miss Nellie Bartingale There were no children of the marriage He died on April 24, while attending the funeral of a friend with whom he had served in India

DAVID JONES THOMAS
M R C S, D P H

Dr Thomas, who died at Salisbury on May 4, at the age of 84, was for more than thirty years medical officer of health for Acton He was born in Newcastle Emlyn, Carmarthenshire, and qualified at the London Hospital in 1899 After serving as Sir Frederick Treves's house-surgeon, he took the D P H in 1900 and was appointed M O H at Merthyr Tydfil the same year In those days outbreaks of smallpox and typhoid fever were commonplace, and Dr Thomas even encountered an epidemic of typhus In 1907 he was appointed M O H for Acton He held this post at a time when many advances in preventive medicine were being made and he was one of the pioneers of diphtheria immunisation

A colleague writes

Dr Thomas will be remembered as an intensely patriotic Welshman, a man of deep religious convictions, and a distinguished freemason His hobby was the study of early parochial registers He married Gwladys Roberts, the Welsh singer, and cared for her during her long illness until her death last year They had four children, two of whom are doctors Dr Thomas's life was one of hard work and unselfishness Many Welsh folk will hear of his passing with "hiraeth"

Dr GEORGE AUDEN

P R K writes

It is now nearly 30 years since Dr Auden first welcomed me to Birmingham as a very junior colleague of his, and from then till his death I had the benefit of his inspiring friendship His learning, his clarity of thought, his energy, and the simplicity—even austerity—of his life were known far and wide To have had his friendship was a privilege Such men are rare indeed, and I for one will never forget *Ave atque vale*

Notes and News

A NEW CUMBRIAN HOSPITAL

In 1945, the hospital survey of the North West recommended to the Ministry of Health that West Cumberland was the one area where permission should be given for building a new hospital It is an isolated industrial area with a population of 140,000, nearly 40 miles from the nearest alternative hospital centre The present hospitals are small and uneconomical, and provide a total of 400 beds where (according to Ministry standards) 900 are needed Moreover, industrial developments (including the atomic centre at Sellafield) are causing an influx of population, and an existing hospital block for geriatric patients has had to be abandoned because of subsidence damage

Two possible sites in the area were vested in the Minister, of which one was in use as a park The other (acquired by the trustees of Whitehaven Hospital before 1939) was chosen it lies on the Millom Road, 2 miles from the centre of Whitehaven. The hospital is to contain 438 beds and will cost some £3 million It will provide for special illnesses not otherwise catered for in the area, and it is expected that patients needing special investigation will gravitate there The Workington Infirmary is being enlarged to become a hospital of 170 beds, to deal with most of the routine medical and surgical work in the borough and an increasing proportion of elderly sick patients

The work is planned in stages, of which the first (conversion of the mansion house on the site to a 41-bed unit for tuberculosis and chest disease) is complete The second will include the erection of all the one storey buildings (geriatric, mental-illness, and infectious disease units, and ancillary services), this will be complete in the autumn of 1959 The third provides for the main hospital block with wards accommodating the major specialties, and operating-theatres and laboratories The fourth will see the erection of a 40 bed maternity unit, the present maternity accommodation at the old Whitehaven Hospital should suffice until this stage is reached

Difficulties in staffing are expected The phasing of the construction should help to solve these by allowing gradual recruitment The nurse-training school in West Cumberland has been reorganised and a recruiting drive is to be launched A new school for assistant nurses has been set up at Workington and a new school of radiography at Carlisle, and the number of laboratory technicians in training has been increased

The tuberculosis block was opened formally on Jan 17 The last phase should be complete and the hospital fully occupied in the summer of 1963

WORKING PATIENTS

Since 1954 the men patients at Fulbourn Hospital, Cambridge, have been gradually drawn into a more active way of life As the report of the hospital for 1956 shows, the benefits of occupation are already becoming apparent and the shape of the new life of the hospital has begun to emerge Although the number of men treated has risen by 26% over the past two years, the number of resident men patients has fallen by 8% and in 1956 stood at 341 13 patients (11 of them long stay) were going out to work every day, during the year 37 patients had gone out to work of whom 17 were discharged (including 4 long stay patients) The work included such jobs as aircraft fitter, meat-pie packer, and cement-worker They have ' all lived a fuller life mixed with the outside world and earned useful money " Indeed during 1956 they contributed £1600 to the hospital for their keep Other patients have worked inside the hospital on piece work such as packing car radio fittings, soldering electrical joints for television aerials, and surfacing wireless fronts

The effort to find more occupations for the women patients began later and is not yet so far advanced, but the wards are already quieter, and there is less sedation and incontinence It is doubtful whether it will be possible greatly to reduce the number of long stay women patients, for nearly half of all the women patients are old age pensioners, and over a quarter of them have been in the hospital for more than twenty years The longevity of women and modern drugs are gradually filling the hospital with aged long term women patients few of whom really need psychiatric nursing, and, as the report wistfully points out until alternative care is offered to these patients Fulbourn will be unable to get on with what is really its proper work—the treatment of the young housewives and middle aged mothers with families who need temporary psychiatric help

TUBERCULOSIS CONTACTS AT WORK

Dr F A Nash, medical director of the South-West London Mass X-ray Service, has lately reported [1] a series of surveys of firms one of whose employees has contracted tuberculosis This was done in two ways (1) when a chest physician notified a case of tuberculosis, he told the director of the mass X-ray service where the patient was last working, and the firm was then offered mass radiography in the usual way, without mention of the reason (2) all firms covered by the service in the area were asked to approach the service when a case of tuberculosis was diagnosed

In the first group, by the end of 1955 thirty-two firms had been visited and 63% of the 12,326 employees radiographed 85 people (1 1%) were found to have lesions, probably tuberculous, needing clinic supervision In the second group nineteen firms were visited 62% of their 11,107 employees were radiographed, and 49 (0 7%) had lesions needing supervision

The age and sex composition of these firms were similar to those of firms examined in routine surveys, where the incidence of cases found is typically 0 44% in the same area On the other hand, the proportion of employees who had not been radiographed before was much higher (44% as against 26 5%) *No other obvious factor (such as poverty or bad working-conditions)* differentiated the firms where these contacts were found from others Probably they are firms which have not been visited by mass X-ray units Findings in the surveys also suggest that radiography of his workmates protects the individual from contact with infection

University of Oxford

On May 2 the following degrees were conferred

D M—E J L Lowbury J D L Reinhold, W H Taylor, W R T Turner

B M—D S Ellis I A Riley (in absentia)

On June 26 the honorary degree of D.LITT will be conferred on Dr J F Fulton, Sterling professor of the history of medicine in the University of Yale

University of Cambridge

On May 4 the degree of M B was conferred on D H H Metcalfe

University of Birmingham

Prof A P Thomson's term of office as dean of the faculty of medicine has been extended to Sept 30, 1959 He will then be succeeded by Mr A. L d'Abreu, part-time reader in thoracic surgery and consultant surgeon to the United Birmingham Hospitals

The following have been given the title of university clinical lecturer

Obstetrics and Gynæcology—Dr H Roberts

Anæsthetics—Dr Ann A Guest, Dr J M. Inglis, Dr R E Lee, and Dr W L Price

Radiology—Dr P Jacobs and Dr C P Moxon

Royal College of Surgeons of England

At a meeting of the council on May 9, with Sir Harry Platt, the president, in the chair, the Cecil Joll prize was presented to Prof P R Allison (Oxford)

Dr G G Lyttle, Dr G F Burnell, Dr R F Guymer, Surgeon Vice Admiral R C May, and Prof P K. Chanmugam were admitted to the fellowship, having been elected as medical practitioners of twenty years standing

A Jacksonian prize was presented to Mr Alan H. Hunt and a certificate of honourable mention to Mr R E Horton. The Gilbert Blane medal for 1957 was awarded to Surgeon Commander S Miles, and the Begley prize to Miss Sybil Birtwistle

Postgraduate diplomas and diplomas of membership were conferred on the candidates named in the report of the comitia of the Royal College of Physicians (*Lancet*, May 4, 1957, p 942) A diploma of membership was also conferred on J J. Key

British National Conference on Social Work

The theme of this conference's meeting in Edinburgh from Aug 11 to 14 is to be children and young people The chairman will be Prof Alan Moncrieff Other medical speakers will include Prof Richard Ellis, Dr G W Ireland, and Sir Sydney Smith Further particulars may be had from the secretary of the National Council of Social Service, 26, Bedford Square, London, W C 1

Royal College of Surgeons of Edinburgh

At a meeting of the college held on May 10, with Sir Walter Mercer, the president, in the chair, the following were admitted to the fellowship

B M Andrea A C Arulpragasam J R Badger D D Beard, K S Brearley J J Breitenbach Madhav Ramchandra Chaudhary, J E *Choo* Kenneth *Clark*, I A Coombes, K B Cornwell, R G Denniss J A Doig, G R Gordon Syed Abdullah Hussaini, Kevin *Johns Rasmus de Ramner Jooste*, Koratti Ardhanariswar Kalyanam I J Kaplan L P Bandara Kiriella, Bernard Lotzof, H L J Lusby, D O MacPhail, E Matthews, F A Meintjes P R Myerscough J G B Myles, C V Petersen, W H Raynham, A A Roux J N Segelov, Marakada Venugopal Shetty, Tribhuan Pati Singh M D M Staunton, I B Taft Ram Narayan Tiwary, Cyril Toker W K M C Watkins, H G Watts, D W Whiteway G B Wylie

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty on May 6, with Prof Stanley Alstead, the president, in the chair, the following were admitted fellows of faculty

Varghese Benjamin J W Howie (*qua* physician) B T Hammond J D L Kirstein, C J Longland, Maung Shwe Tin (*qua* surgeon)

Birmingham Medical Institute

This institute will close its library and office at 154, Great Charles Street on May 17 and will reopen on Monday, May 27, at 36, Harborne Road, Edgbaston The local offices of the following organisations also will move to 36, Harborne Road Birmingham Local Medical Committee, British Medical Association, Medical Insurance Agency, and Medical Benevolent Society

World Health Organisation

Dr W Aeg Timmerman has been appointed assistant director general in charge of central technical services, in succession to Dr H S Gear

Born in The Hague in 1893 Dr Timmerman studied at the University of Leiden and worked for several years at the Institut Pasteur in Bandung, Java before he was appointed in 1934 director of the national institute for public health in the Netherlands He held that position until 1950 when he joined the staff of W H O as director of the division of therapeutic substances

Dr Gear is remaining in Geneva to complete some technical studies on behalf of W H O

Clean Air Council

This council has now been set up, under section 23 of the Clean Air Act, 1956, to help the Minister of Housing and Local Government to keep under review the progress made in abating the pollution of the air in England and Wales, and to obtain the advice of people with special knowledge, experience, or responsibility of prevention of pollution The Minister himself will be chairman, and his parliamentary secretary and the parliamentary secretary of the Ministry of Power vice-chairmen The 29 members appointed include Dr C A Bence, a Cardiff alderman, Dr Llewelyn Roberts, M O H for Sheffield, and Prof A B Semple, M O H for Liverpool

General Practice Reform Association

Among resolutions passed at the third annual general meeting held in London on May 4 were

That this meeting welcomes the fact that the Royal Commission is prepared to consider evidence on the remuneration of assistants in general practice

That the 5% interim increase in general practitioner remuneration should be distributed so that as in the case of the hospital doctors those with the lower incomes will receive a higher percentage increase

That the minimum permitted share for a junior partner in any general practice partnership in the National Health Service should be not less than one half of the largest share in the partnership and that an incoming partner's share should be required to reach parity or near parity with that of the other partner(s) in not more than five years from the date of his admission to the partnership

Medical Research Society

Dr Stanley F Bradley, of Columbia University, will deliver a lecture to this society on Friday, May 31, at 5 30 P M at the London School of Hygiene, Keppel Street, W C 1 He is to speak on circulatory adjustments to postural changes

National Society for Mentally Handicapped Children

The annual convention of this society is to be held at County Hall, Westminster Bridge, London, S E 1, on Saturday, May 25, at 10 45 A M The speakers will include Prof R S Illingworth Further particulars may be had from the society, Kingsway Chambers, 162A, Strand, W C 2

British Association for Physical Medicine

At the annual general meeting held at the Middlesex Hospital, London, on April 6, with Dr P Bauwens, the president, in the chair, the following officers and new members of council were elected

Vice president Dr H A Burt, hon treasurer Dr Donald Wilson, hon secretary, Dr G O Storey hon editor, Dr A C Boyle council Dr H J Glanville, Dr S Mattingly, and Dr N R W Simpson

Registers of Medical Auxiliaries

The Board of Registration of Medical Auxiliaries has published new editions of its registers of dispensing opticians, orthoptists, and operating theatre technicians The board also maintains registers of chiropodists and radiographers, and a register of audiology technicians is in course of preparation Copies will be supplied free to doctors on application to the registrar of the board, B M A House, Tavistock Square, London, W C 1

National Birthday Trust Fund

In 1955 the trust set up a steering committee with observers from the Ministry of Health, Department of Health for Scotland, and Welsh Board of Health, and representatives of the Royal College of Obstetricians and Gynæcologists, the British Medical Association, the Society of Medical Officers of Health the College of General Practitioners, and the Royal College of Midwives to consider how best to carry out a survey into stillbirths and infant deaths in the first week of life The *committee have approved the proposals for this* perinatal survey and it is hoped, with the permission of medical officers of health and obstetricians, to invite midwives to collect the information about all births under their care during one week in November and to obtain additional details from the health visitor about the state and health of the baby when it is a few weeks old A pilot scheme has already been carried out in Nottingham

LEUKÆMIA *

RONALD BODLEY SCOTT
MA, DM Oxfd, FRCP
PHYSICIAN TO H M THE QUEEN, PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL

THE topic I have chosen is a latter day affliction, and a glance at the titles of previous Lettsomian lectures shows that leukæmia has never before been their subject. I am, moreover, denied the conventional gestures of filial piety, because it was not until twenty-six years after the death of John Coakley Lettsom that Barth and Donné, at the Hôtel Dieu in Paris, noted "the remarkable predominance of mucous globules" in the blood of a patient with splenic enlargement Their observation was not published for many years (Donné 1844), and the first recorded examples of leukæmia are to be found in the *Edinburgh Medical and Surgical Journal* of Oct 1, 1845, where David Craigie and John Hughes Bennett separately reported cases of hypertrophy of the Spleen and Liver in which Death Took Place from Suppuration of the Blood A few months later Rudolf Virchow (1845) described a case of "Weisses Blut," and there followed an acrimonious wrangle over priority, the faint echoes of which were audible as late as 1885, when William Osler cast the deciding vote for Virchow Undoubtedly Virchow had more insight than his rivals into the nature of the leukæmic process, and in 1847 he introduced the word "leukæmia" and distinguished splenic and lymphatic varieties He had, in Osler's words, "vindicated a place in pathology for the white blood corpuscle"

Although acute leukæmia was described by Friedrick a hundred years ago (1857), further advance awaited Paul Ehrlich's (1891) introduction of specific methods of staining the leucocytes These permitted the recognition of the myeloblast by Otto Naegeli in 1900 and the separation of the cytological varieties of leukæmia Monocytic leukæmia, the last of these to be identified, was not described until 1913 (Reschad and Schilling 1913)

Although leukæmia is something of a parvenu with barely a hundred and twenty years of respectable ancestry, it has recently become the focal point of hæmatology Its inevitably fatal outcome and the youth of many of its victims have aroused the interest and sympathy of the physician and have stirred the emotions of the public, it provides the research-worker with a fertile field for his ventures in the chemotherapy of cancer, and the problems of its ætiology have become the concern of the epidemiologist, the statistician, and the radiologist

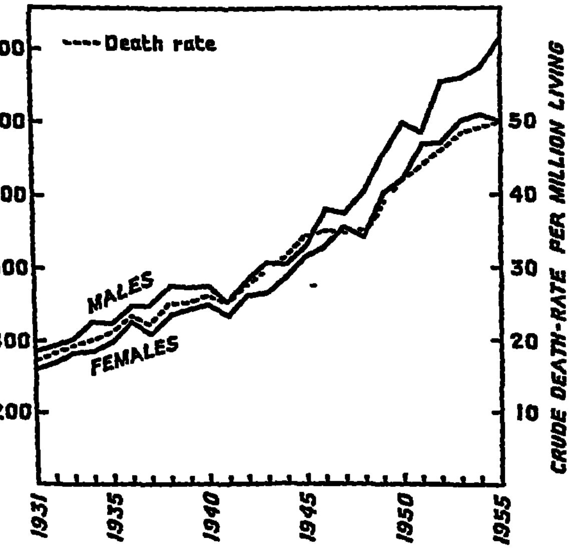

Fig 1—Mortality due to leukæmia in England and Wales 1931–55

These lectures can do little more than touch on some aspects of a subject which has become immense, in the main they will be a record of personal experience of leukæmia, viewed from a clinical and therapeutic standpoint The present series of some 570 patients has not been collected consecutively, it is undoubtedly weighted by selection, and it must not be regarded as a representative sample of the general leukæmic population Nevertheless the patients with acute leukæmia form a consecutive series, and those with the chronic varieties, being unselected, may be claimed as fair examples of the totality of sufferers from these diseases

Incidence of Leukæmia

The disease is still uncommon but its incidence, in all countries from which statistics are available, has shown a steady increase during the past twenty years In England and Wales the crude death-rate per million living was 17 in 1931 and 50 in 1955, or, in absolute numbers, 685 persons were certified as dying from leukæmia in 1931 and 2224 in 1955 (Registrar-General 1956) (fig 1)

At all ages below 65 the number of males dying from this cause exceeds the number of females From 1931 to 1955 the major increase has been in older patients, the age-distribution in 1940 and 1954 are contrasted in fig 2 Similar changes have been reported from other countries (Cooke 1954, Lancaster 1955, Phillips and Owchar 1955, Gunz and Hough 1956) The only two causes of death which have shown a greater rate of increase during this period are carcinoma of the lung and coronary thrombosis

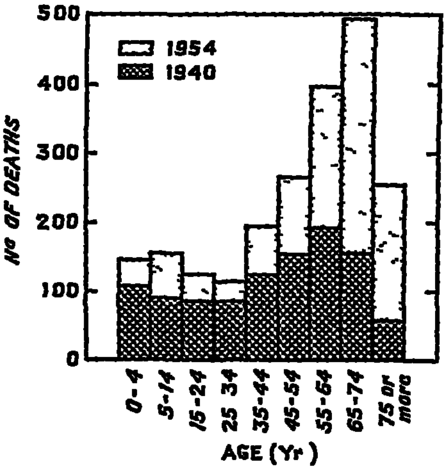

Fig 2—Age-distribution of deaths due to leukæmia in 1940 and 1954

Other vagaries in the incidence of leukæmia are a preponderance of urban over rural dwellers, of well-to do over less well to do, and, in the United States, of white over coloured—although this difference is considerably less when the ages are standardised (Hewitt 1955, Meadors 1956)

It seems likely that more precise diagnosis explains some of this increase but certainly not all It must be accepted that the incidence of the disease is steadily rising

There is still difficulty in estimating the incidence of the various types of leukæmia The variations shown in table I are probably to be attributed to selection, although local differences may play a part

Ætiology of Leukæmia

The nature of the leukæmic process is now generally held to be neoplastic, and, when "cancer" is defined in

---

* The first Lettsomian lecture for 1957, delivered before the Medical Society of London on Feb 11 The second and third will appear in forthcoming issues

TABLE I—INCIDENCE OF MAIN VARIETIES OF LEUKÆMIA

Reference	No of cases	Acute (%)	Chronic myeloid (%)	Chronic lymphatic (%)	Undetermined (%)
Wintrobe (1956)	2424	40 1	29 0	30 9	
Gunz and Hough (1956)	553	62 3	17 5	14 5	5 7
MacMahon and Clark (1956)	1636	44 5	19 [illegible]	21 3	11 5
Gauld et al (1953)	647	41 9	26 [illegible]	32 0	

terms of dynamic cell behaviour, there can be little quarrel with this view It is undeniably a purposeless progressive uncoordinated cellular proliferation, superfluous to the needs of the host, and continuing after the evocative stimulus (if one can be identified) has ceased to operate As in other forms of cancer, the abnormality seems to reside within the cells themselves, which exhibit an unrestrained and undisciplined capacity for reproduction The fundamental cause of leukæmia is thus to be sought in the larger mystery of the cause of cancer, and at present we can only fruitfully inquire into the influences which may play some part in initiating this disorder of cellular behaviour

External Agents

In man the only external agent whose importance has been established is ionising radiation Some of the evidence for this contention, which seems irrefutable, is as follows

The incidence of leukæmia in survivors of the atomic bomb in Hiroshima has been four and a half times that of the general population of Japan Its frequency in those severely irradiated at less than 2500 metres from the hypocentre of the explosion was 1 in 172, whereas in those outside this radius it was only 1 in 12,912 (Moloney 1955, Moloney and Kastenbaum 1955)

In patients with ankylosing spondylitis treated by irradiation the deaths from leukæmia amount to between ten and twenty times the expected number (Court Brown and Abbatt 1955, Abbatt and Lea 1956, Court Brown and Doll 1956)

There are reports of leukæmia in patients previously irradiated for thymic tumours or treated with radioactive iodine for thyrotoxicosis (Blom et al 1955, Abbatt et al 1956, Pochin et al 1956)

The mortality from leukæmia in radiologists between the ages of 35 and 74 is three and a half times that of other members of the medical profession, and eight and a half times that of all white males of the same age (Peller 1952)

Diagnostic radiology of the pelvis in pregnancy may increase the chances of leukæmia appearing in the child (Stewart et al 1956)

The evidence that other agents may be leukæmogenic is less convincing

The best attested is perhaps chronic benzene poisoning, the causal efficacy of which is accepted in France as beyond question (Bernard and Braier 1951) I have experience of an instance in which two men were exposed to the fumes of benzene one developed an aplastic anæmia from which he recovered, and the other died from acute myeloblastic leukæmia

Acute leukæmia following marrow aplasia due to chloramphenicol has been recorded (Lebon and Messerschmitt 1955) It has also been reported after agranulocytosis due to sulphonamide (Wilkinson 1955) It seems probable that regeneration of the bone marrow after severe injury may transcend the physiological and assume neoplastic characters

The termination of idiopathic aplastic anæmia in acute leukæmia is well recognised (Wintrobe and Mitchell 1940, Black and Meynell 1951), and I have observed it on 3 occasions

Heredity

A genetic basis for leukæmia has been suggested by the occasional report of several cases in one family

Videbæk (1947) obtained a family history of the disease in 8% of 209 patients, it was particularly frequent in the chronic lymphatic form

Analyses of larger series have not confirmed his claims, Guasch (1954) noted consanguineous leukæmia only 39 times in 8586 collected cases, an incidence of 0 5%

Of my patients, there was a family history of leukæmia in 3 of 228 with chronic lymphatic leukæmia but in none with the other varieties In 1 patient the disease appeared within six months of the death, from the same cause, of her mother, whom she had nursed

There are several records of twins, uniovular and binovular, both developing leukæmia (Cooke 1953, Anderson and Hermann 1955) As a random event it has been estimated that this would happen once in a hundred and fifty years in the United States

It seems likely, therefore, that genetic factors are sometimes operative, but their importance cannot be great

Zoological Distribution

Leukæmia has been reported in almost every species of the animal kingdom, from the vulture to the sea lion (Engelbreth Holm 1942) The relation between the human and animal forms of the disease remains uncertain, but much investigative effort has been expended on the second in the hope of shedding light on the first Most of the research has been directed towards discovery of the cause As long ago as 1908 it was proved that fowl leukæmia was due to a virus which invaded the blood cells and apparently endowed them with malignant qualities (Ellerman and Bang 1908) Beard (Bonar et al 1956) has recently been able to show that there are two distinct, but closely related, viruses which are responsible for avian myeloblastosis and erythroblastosis *No other leukæmia is yet established as due to a virus*

Mouse leukæmia has been the most commonly used for research The mouse is particularly liable to a lymphatic form of the disease, and the importance of genetic factors is shown by the breeding of strains in which 60–70% of individuals eventually die of spontaneous leukæmia It is generally held that transmission is possible only when live cells are inoculated, although recently Gross (1953) and others have claimed successful passage with cell free filtrates A number of different agents apparently influence the incidence of the disease and the susceptibility of animals to inoculation

The application of these observations to the problem of the cause of leukæmia in mice is sufficiently obscure and their relevance to human disease quite unproven Some believe that the agents mentioned disturb cellular equilibrium in a way which initiates the leukæmic process, and that, once established, this perpetuates itself Others cling tenaciously to the viral hypothesis, among these are Schwartz et al (1956), who claim to have recovered from the brains of some patients dying from leukæmia an agent which will accelerate the development of the disease in a susceptible strain of mice

ACUTE LEUKÆMIA

Incidence of Cytological Types

Acute leukæmia is distinguished from the chronic form by the immaturity of the proliferating cells and the rapidity of its course Myeloblastic, lymphoblastic, and monocytic varieties are recognised, but the distinction between the several primitive elements may be difficult, and refuge is often sought in the evasive qualification of

TABLE II—DISTRIBUTION OF 169 CASES OF ACUTE LEUKÆMIA BY CYTOLOGICAL TYPES

Cytological type	Male	Female
Myeloblastic		
"Classical" type	35	44
Erythromyelosis	2	[illegible]
Lymphoblastic		
"Classical" type	23	9
Pure medullary type	10	5
Sternberg type	7	1
Monocytic	12	11
Erythræmia (Di Guglielmo 1926)	4	1
Total	93	76

TABLE III—INCIDENCE OF CYTOLOGICAL TYPES OF ACUTE LEUKÆMIA

Reference	No of cases	Myeloblastic (%)	Lymphoblastic (%)	Monocytic (%)	Undetermined (%)
Rosenthal and Harris (1935)	173	77 4	18 5	4 1	
Gauld et al (1953)	271	25 2	53 4	21 4	
Gunz and Hough (1956)	346	38 2	37 6	2 0	22 2
Present series	169	49 7	33 7	13 6	

"stem cell" There is, therefore, considerable variation in the reported incidence of the different types The present series is not to be regarded as unselected, because leukæmia in childhood is the province of the pædiatrician, and it consequently contains a disproportionate number of adults (table II) This has the effect of reducing the numbers of the lymphoblastic variety, which is particularly common during the first decade The variability of reported series is shown in table III

More males than females fall victim to acute leukæmia, an inequality due to the frequency of the lymphoblastic type in male children The age-incidence of the three varieties shows striking differences (fig 3) Myeloblastic leukæmia is spread evenly throughout the whole span of life, lymphoblastic is predominantly a disease of children, and monocytic affects mainly the middle aged

Clinical Picture

A detailed clinical description of acute leukæmia would be inapposite, and the following account is but a summary review The different cytological varieties seldom present clear-cut clinical differences The ingredients which go to make up the picture are anæmia, a hæmorrhagic state, enlarged lymph-nodes, spleen, and liver, sometimes with infiltrations in other tissues, and secondary infective phenomena The accent may fall sometimes on one and sometimes on another of these features

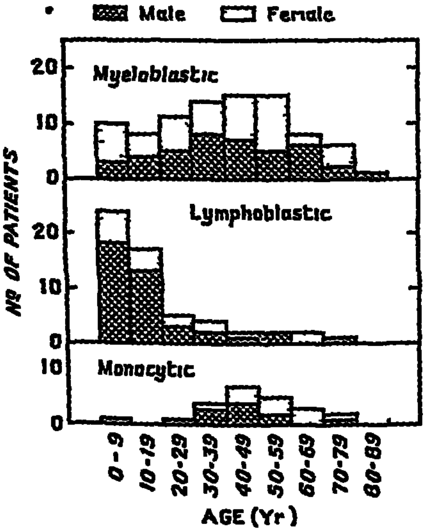

Fig 3—Age-incidence of acute leukæmia.

Myeloblastic Leukæmia

In myeloblastic leukæmia the presenting symptom is usually anæmia, often of insidious onset and often combined with a hæmorrhagic state The spleen may be felt, but lymph-node enlargement is unusual Skin infiltrations, usually papular, are not rare In children subperiosteal chloromatous tumours are occasionally noted Fever is common, and this is more often the result of infection than was previously believed Spongy gums, with ulcerated margins oozing blood, are a familiar feature

Lymphoblastic Leukæmia

Lymphoblastic leukæmia presents in one of three clinical guises anæmia combined with lymph-node enlargement, splenomegaly, enlargement of the liver, and infiltrations in various tissues, may be called the "classical" form of the disease The second, or pure medullary, type is common in young children Here anæmia and perhaps a hæmorrhagic state are the only initial signs There is no enlargement of the liver, spleen, or superficial lymph-nodes In this variety pain in bones and joints is often a prominent symptom, and many patients are admitted to hospital with a diagnosis of rheumatic fever or osteomyelitis The third variant, or the Sternberg type, has been described as acute lymphosarcoma-cell leukæmia, although there seems to be no justification for excluding it from the present category The patient presents with a nodal tumour, usually in the mediastinum, but in 1 of my patients it was in the nasopharynx At this stage the blood-count may be normal, but within a few days to a few weeks lymphoblasts have invaded the blood, the total leucocyte count has risen, perhaps to 200,000 per c mm, and anæmia and thrombocytopenia have made their appearance Some authors believe that the predominant cell in this variety can be distinguished from the lymphoblast of other types of acute lymphoblastic leukæmia

Monocytic Leukæmia

Monocytic leukæmia differs little from myeloblastic in its clinical features, except in its particularly frequent association with gingivitis and stomatitis The cervical lymph-nodes may be enlarged, but rarely are those of other groups affected, the spleen is usually not palpable

Other Forms

Sometimes the anaplastic process affects the precursors of the red blood cells exclusively, and the resulting disorder is termed acute erythræmia or Di Guglielmo's disease (Di Guglielmo 1926) Intermediate forms marked by myeloblastic and erythroblastic proliferation are spoken of as acute erythromyelosis In many instances these cytological changes are transient and later give place to a pure myeloblastic proliferation Their clinical features do not separate them from acute leukæmia *sensu stricto*, fever, profound anæmia, splenohepatomegaly, and a hæmorrhagic state accompany their rapidly progressive decline

Occasionally acute leukæmia declares itself after a long period of ill health whose features have been those of aplastic anæmia, chronic neutropenia, or thrombocytopenia This initial illness has been termed "pre-leukæmia," but the relationship to the conventional form of the disease is uncertain (Block et al 1953) 3 cases of this variety have been excluded from the present series as well as 1 case each of polycythæmia and myelosclerosis terminating in acute leukæmia

Blood Picture

The diagnosis of acute leukæmia is established only by examining the blood and bone marrow Some anæmia is constant The peripheral leucocyte count varies, indeed, leucopenia is rather more common than the high counts previously regarded as characteristic Whatever the total, a proportion of primitive cells is almost always found Thrombocytopenia may be absent in the early stages but with progress of the disease it is invariable

When the changes in the peripheral blood are inconclusive, the diagnosis is established by bone marrow puncture, which will reveal in almost every instance a replacement of the normal cells by myeloblasts, lymphoblasts, or primitive monocytes The interpretation of the erythroblastic, or mixed erythroblastic and myeloblastic, proliferations of Di Guglielmo's disease and erythromyelosis may be difficult to those unfamiliar with these less common variants

Treatment

The management of patients with acute leukæmia presents the physician interested in hæmatology with his greatest challenge The disease remains obstinately fatal, and it has been suggested that humanitarian considerations should forbid attempts to procure remission which can never be more than transient. There can, however, be no doubt in the minds of those who see many of these patients that such an attitude is indefensible. This nihilistic approach demoralises the patient, his relatives, and his medical attendant; moreover it erects an impenetrable barrier against therapeutic advance. Even a few more months of life may be immeasurably precious, and it is the physician's duty to do all that is possible to procure this temporary reprieve.

The fundamental aim of treatment is to control the neoplastic process and restore normal cellular behaviour in the hæmopoietic system; but, before the measures aimed at this goal are described, symptomatic treatment must be considered.

SYMPTOMATIC TREATMENT

The patient with acute leukæmia is a ready victim of infections, general and local. Septicæmia should always be suspected when there is high fever, and, if blood-culture establishes its presence, the appropriate antibiotic should be prescribed. 2 recent patients, in whom complete remissions were later procured, presented with general infections by *Streptococcus hæmolyticus* and *Staphylococcus pyogenes*. Local infections of the mouth, respiratory tract, and skin demand bacteriological identification and the correct antibacterial agent. Monilial invasion of the mouth, throat, and œsophagus is particularly frequent, especially when steroid hormones are used; in such cases 'Nystatin' has proved invaluable. Mouth-washes of 1.5% hydrogen peroxide or of a saturated solution of sodium perborate do much to relieve the discomfort of leukæmic stomatitis.

Routine or prophylactic use of antibiotics is inadvisable. These drugs should be prescribed only when the generally accepted indications exist, and the discomfort of intramuscular injection in the patient with a hæmorrhagic state must be borne in mind.

The importance of the tendency to bleed is shown by the fact that, in 23 of 55 patients examined post mortem, hæmorrhage had apparently been the immediate cause of death, and in 14 of them the bleeding had been intracranial. There is a close parallel between the platelet count and the tendency to bleed; but it is common to see thrombocytopenia without significant bleeding for weeks, or even months, terminating in an explosive and rapidly fatal hæmorrhagic state. It is possible that this sudden change is sometimes brought about by the appearance of a fibrinolysin or a circulating anticoagulant, either of which may owe its origin to bacterial invasion (Freeman 1952). The control of infection is therefore important in control of the hæmorrhagic state. Other measures are of little avail: simple blood-transfusion is seldom effective, but platelet transfusions have some transient benefit, although they rapidly lose their virtue (Stefanini and Bernfeld 1953). The steroid hormones may temporarily decrease the tendency to bleed. Intravenous injections of a chloroform extract of acetone-washed brain may prove valuable (Hayhoe and Whitby 1955).

Electrolyte disturbances are common in the acutely ill leukæmic patient and require correction. A low serum potassium level has been noted in several cases (Videbæk 1951), and in 1 case many of the symptoms were due to hypercalcæmia (Mawdsley and Holman 1957).

Blood-transfusion is the only method of relieving anæmia, but there is some evidence that it may have a more profound effect. Remission has often been noted to follow it (Dreyfus 1948) and this observation was the rationale for exsanguination transfusion, which enjoyed a certain therapeutic vogue a few years ago (Bessis and Dausset 1950). Its action has more recently been attributed to liberation of adrenal steroids as the result of transfusion shock (Bessis 1954). This point has again been underlined by a report of remissions thus induced in 34% of 41 patients (Hayhoe and Whitby 1955). In the present series significant remissions were noted in 9 (19.5%) of 46 patients treated by transfusion alone. Exsanguination-transfusion was undertaken in only 3, but in none of these was the course of the disease obviously altered.

Blood-transfusion has no place as a definitive means of treatment, but it should be prescribed in quantities sufficient to maintain a hæmoglobin level of 9 g. per 100 ml. while attempts are made to control the leukæmic process. It should always be a purposive measure and not a resort *faute de mieux*.

SPECIFIC MEASURES

The agents which may exert partial or complete, although never more than temporary, control over the leukæmic process are the steroid drugs and certain antimetabolites.

Steroid Hormones

Cortisone was shown to inhibit the growth of transplanted lymphosarcoma in mice as long as thirteen years ago (Heilman and Kendall 1944), but it was not used in human leukæmia until 1950 (Farber et al. 1950, Pearson et al. 1950). Analysis of published series shows that of 425 patients treated with cortisone or corticotrophin there was complete remission in 29% and partial in 24% (Fessas et al. 1954). The expression "complete remission" is defined as a disappearance of all symptoms and physical signs of disease, the restoration of a normal blood picture, and the presence in the bone marrow of the sum of "blast" cells and lymphocytes in a proportion of less than 20% of the total. Subsequent experience has shown that complete remission may be expected in children with lymphoblastic leukæmia and not rarely in adults with this form of the disease. In myeloblastic leukæmia it is less commonly obtained in children and in adults rarely. Monocytic leukæmia never responds.

There is, indeed, some evidence that steroid hormones may accelerate the leukæmic process in the last named forms (Fessas et al. 1954). In the present series the results obtained with cortisone or corticotrophin are set out in table IV.

TABLE IV—RESULTS OF TREATMENT OF ACUTE LEUKÆMIA WITH STEROIDS

Cytological type	No. of cases	Remissions	
		Complete	Partial
Myeloblastic			
Adults	13	1	1
Children	5	2	2
Lymphoblastic			
Adults	10	4	2
Children	10	6	2
Monocytic			
Adults	4	0	0
Total	42	11	7

The daily dose of cortisone required is 200–300 mg. in adults and up to 200 mg. in children. Corticotrophin is given by intramuscular injection every six hours in daily doses of 200 mg. for adults and 100 mg. for children, or by intravenous infusion in quantities of 25–50 mg. in eight to twelve hours. Some workers have claimed more satisfactory results in adults by using prednisolone in a dosage as high as 5 g. daily (Hill et al. 1956).

Remission with steroid drugs is usually established in the third or fourth week of treatment. It seldom lasts more than six weeks, and relapse is not prevented by maintenance dosage. If treatment is intermittent second remissions may sometimes be obtained in children, but rarely in adults.

Antimetabolites

An antimetabolite is an agent which obstructs the working of an enzyme system By virtue of its chemical similarity to the metabolite or raw material of the system in question, it becomes united with the enzyme It differs, however, sufficiently from the enzyme to prevent the reaction from proceeding to completion A chemotherapeutic spanner has been thrown into the metabolic works, the pathway is blocked and deficiency of the essential final product results The antimetabolites which have proved of value in acute leukæmia are those which *interfere with the synthesis of nucleic acid*

Folic-acid antagonists—The first to be used were the folic acid antagonists The step was taken empirically after the observation that the leukæmic process was accelerated by giving a folic acid conjugate (Farber et al 1948) Those in common use are the 4-amino antagonists of pteroylglutamic acid (folic acid) aminopterin (4-amino pteroylglutamic acid) and amethopterin or methotrexate (4 amino-N^{10}-methylpteroylglutamic acid) These drugs prevent the conversion of pteroylglutamic acid to citrovorum factor and, by interfering with the action of the second, impede the synthesis of nucleic-acid purines

The folic acid antagonists have little or no place in the treatment of adults, but in children remission is procured in 60–70% of cases of lymphoblastic leukæmia (Burchenal 1952, Fountain 1954) They are given by mouth aminopterin in doses of 0 5–1 0 mg daily in children and up to 3 mg a day in adults, and methotrexate in doses of 2 5–5 0 mg and up to 10 mg a day respectively Remission may not appear for eight weeks, it may endure for as long as two years, but the mean lies between two and three months Second remissions may occur, but resistance finally develops Severe toxic symptoms are not uncommon and may supervene in a few days or be delayed for months the earliest is stomatitis, followed by diarrhœa, vomiting, loss of hair, and sometimes gastro intestinal hæmorrhage

The folic acid antagonists have not been used extensively in this series Partial remission was obtained in 3 of 5 children with myeloblastic, and in 2 of 6 with lymphoblastic, leukæmia 1 of 2 adults with monocytic leukæmia had a short incomplete remission

Mercaptopurine—Many other antimetabolites have been subjected to clinical trial, but the only ones of proved value are the purine antagonists, which interfere with nucleic acid synthesis at a different stage of metabolism The first shown to have an antileukæmic effect was 2 6 diaminopurine (Burchenal et al 1951), but this was rapidly superseded by the more effective 6 mercaptopurine (Burchenal et al 1953) The customary daily dose of this drug is 2 5 mg per kg body weight Three to eight weeks is needed for remission to occur, and toxic effects, other than leucopenia, are rare Treatment is continued until the bone marrow is hypocellular and the sum of lymphocytes plus "blast" cells is below 20% of the total If this has not been achieved at the end of eight weeks the dosage may be doubled, and sometimes a delayed response is noted When remission has been obtained, a maintenance dosage of 2 5–1 25 mg per kg body-weight is continued In this series the smaller dosage has been preferred

Many reports are available of the value of this drug (Conference on 6-Mercaptopurine 1954) In general about a third of the children and about a seventh of the adults treated have shown remission, which lasted from one week for as long as a year, with a mean of three or four months In all cases the disease eventually becomes resistant The chance of remission appears to bear less relation to the cytological variety of leukæmia than when folic acid antagonists are used In the present series 6 mercaptopurine was given to 51 patients with the results set out in table v

TABLE V—RESULTS OF TREATMENT OF ACUTE LEUKÆMIA WITH 6 MERCAPTOPURINE

Cytological type	No of cases	Remissions	
		Complete	Partial
Myeloblastic			
Adults	18	6	3
Children	8	2	3
Lymphoblastic			
Adults	10	5	2
Children	10	5	2
Monocytic			
Adults	5	1	0
Total	51	19	10

Analogues of 6-mercaptopurine, thioguanine, and 6-chloropurine are on trial (Murphy et al 1955) There is some evidence that the second increases the frequency of complete remission in adults (Ellison 1956) In some adults in whom acute leukæmia has become refractory to 6-mercaptopurine a second remission has been obtained with folic-acid antagonists (Ellison 1956)

Azaserine—There is, too, some evidence that a glutamine antagonist, azaserine, will increase the length of remission in children when given with 6 mercaptopurine (Ellison et al 1954, Burchenal et al 1955)

Prognosis

Acute leukæmia remains stubbornly fatal Its course is so variable that figures of average duration have little meaning Analysis of published series has shown that there is no statistical proof of significant increase in the total survival when "specific" drugs are used (Haut et al 1955)

In the present series, in 81 patients treated with blood-transfusion and antibiotics alone the mean length of survival from the first symptom was 20 2 weeks, and in 63 who received in addition "specific" treatment 21 7 weeks These figures provide no cause for optimism, but we have at present 6 patients in complete remission With all humility it may be claimed that there are, at least, grounds for hope and encouragement in this recently acquired ability occasionally to halt for a while the formerly unrelenting malignant process known as acute leukæmia

THE NATURE AND ORIGIN OF THE MAMMOTROPHIC AGENT PRESENT IN HUMAN FEMALE URINE

GEOFFREY HADFIELD
M D Lond , F R C P , F R C S

DIRECTOR OF THE CLINICOPATHOLOGICAL LABORATORIES OF THE IMPERIAL CANCER RESEARCH FUND, LINCOLN'S INN FIELDS, LONDON , *CONSULTING PATHOLOGIST TO ST BARTHOLOMEW'S HOSPITAL*

THE urine of normal premenopausal women, when injected into the intact weanling males of certain strains of albino mice, induces an easily recognisable growth response in their primitive mammary glands Histological studies have shown that the essential feature of this response is a highly significant increase in the rate of proliferation of mammary epithelium (Hadfield and Young 1956a) The urine of 57% of normal postmenopausal women also contains this mammotrophic agent (Hadfield and Young 1956b)

It has been found impossible to induce this growth response to urine in the mammæ of intact weanling males of the large majority of available strains of laboratory mice Of 37 strains examined, in 2 only—S A S 3 and Strong A_2G—were the mammæ found to be sensitive to urinary mammotrophin, although all strains reacted promptly and vigorously to ovarian œstrone The 35 strains in which the intact weanling males were insensitive to urinary mammotrophin proved to be equally insensitive to pituitary prolactin alone On the other hand, the 2 strains in which vigorous mammary growth responses were induced by prolactin also showed an identical response to human female urine (Young 1957) These results suggest, but afford no proof, that the mammotrophic agent present in female urine is pituitary prolactin

Acting on this suggestion a trial series of preoperative tests were carried out on seven patients suffering from metastatic breast cancer in whom hypophysectomy was under consideration The urine of three cases was found *to be mammotrophic, and hypophysectomy* in these was *followed* by unmistakable regression of growth in the tumour and its metastases No regression followed the operation in the remaining four patients whose urine failed to produce a mammary response in intact male weanling mice of a strain known to be sensitive both to urinary mammotrophin and to prolactin

These results are admittedly inconclusive, for the reactions were obtained in intact animals Nevertheless they suggest that an estimation of the mammotrophic potency of the urine, by providing information regarding the mammotrophic function of the hypophysis, might be of assistance in the selection of cases of breast cancer likely to benefit from hypophysectomy Such a test, however, carries serious clinical implications, and it would be unjustifiable to advocate its use *until more* is known about the *organ of origin* of the *mammotrophin in* human urine The investigations reported here were designed to solve this problem

It has been established by Lyons, Li, and their associates (1955), using hypophysectomised rats, that an advanced degree of mammary growth and differentiation can be induced in gonadectomised immature males and ovariectomised virgin females by the injection of ovarian œstrogen and progesterone together with pituitary prolactin in a carefully predetermined dose ratio None of *these hormones alone was capable of inducing* proliferation of mammary epithelium, and combinations of them in pairs proved equally ineffective It is difficult, therefore, to escape the conclusion that the "mammogenic triad" of hormones—œstrone, progesterone, and prolactin—is, in the rat at least, directly and specifically responsible not only for lactogenesis but also for the normal proliferation and differentiation of the mammary epithelium which determines the formation of a functionally competent organ

The general plan of the rat experiments of *Lyons* has been followed in the investigations reported in this paper It has been shown that the epithelial proliferation which leads to mammogenesis in hypophysectomised immature male mice *of the Strong* A_2G strain is totally dependent *on the* synergistic action of the same "mammogenic triad" of hormones as controls this process in the rat As the main purpose of the investigations was to determine the nature and origin of the mammotrophic agent present in human female urine, a second series of experiments was carried out in which the prolactin component of the "mammogenic triad" was omitted and unaltered premenopausal female urines, or extracts prepared from such urines, were injected *in* its place

Methods

Age and Weight of Animals

Males of the Strong A_2G strain weaned *at the age of* 21 days were hypophysectomised *between the* 23rd *and* 28th day the body weight at hypophysectomy varying between 9 and 14 grammes The operative technique used was that of Thomas (1938), in which the base of the skull is reached by a lateral pharyngeal approach and the pituitary exposed by dividing the occipito *sphenoidal synchondrosis,* incising the basi occipital bone transversely 2 25 mm behind the synchondrosis, and removing the rhomboidal panel of bone which lies between the incisions This operation becomes more *difficult as* the weanling grows *and* the skull *base* becomes increasingly ossified *and* therefore *more* vascular

Criteria for Total Ablation

The body weight falls for a few days after total hypophysectomy and then rather slowly rises At the 10th

postoperative day, if total ablation has been achieved, the body-weight has hardly reached the preoperative level but occasionally exceeds it by about 5%. Over the same period, and within the same age range, normal intact untreated A_2G male weanlings were found to show an average gain of 77% of the body-weight. Excluding the animals given prolactin, weight loss, weight stasis, or a gain at the 10th postoperative day not exceeding 5% of the body-weight at operation, was accepted as provisional evidence of total ablation.

Prolactin is contaminated to a varying degree by growth hormone, and hypophysectomised animals given prolactin showed a significantly higher postoperative weight gain than the others, the increase being proportional to the dose of prolactin. A gain not exceeding 7·5% of the body-weight has therefore been accepted as provisional evidence of total ablation in animals given prolactin. On the basis of postoperative weight gain outside these limits, the results obtained in 17% of the hypophysectomised animals have been discarded.

Duration of Injection Period

Two injections of hormones or urine per mouse per day for 5 days were given in all experiments. This does not allow sufficient time for full glandular differentiation and lobule formation in reacting glands, but early acinisation could be clearly discerned in a considerable proportion of them.

Estimation of Mammotrophic Potency

The primitive mammæ of normal intact weanling males grow slowly up to sexual maturity, and in the minority the duct ends show an inconspicuous swelling. Glands in which recent growth acceleration has been induced by hormones or urine show prominent, richly cellular, deeply stained, or partly acinised end-bulbs or "clubs," composed of closely packed undifferentiated epithelium in which mitoses are numerous. Histological studies of weanling male mammæ have demonstrated that the presence of clubs whose diameter is double or more that of their parent duct affords irrefutable evidence of recent and abnormally rapid cellular multiplication induced by a specific exogenous hormonal stimulus. Clubs of this size, including those showing early acinisation, were counted in all the mammæ dissected from animals in each experimental group, and the average number of large, deeply stained "clubs" per gland in the group was estimated. As the mammæ of normal intact weanling males of the Strong A_2G strain bear less than one club per gland (fig. 2, row 1), this figure is taken as being a measure of recently induced growth acceleration and of the "mammotrophic potency" of the stimulus producing it.

Urine and Urinary Extracts

A volume of 0·2 ml. per day per mouse of an untreated early-morning specimen was administered subcutaneously.

Urinary extracts were prepared by a modification of the Lyons method (1934). The dried powder, which keeps indefinitely, was dissolved in a measured volume of normal saline to give a concentration five times greater than urine.

Results

Experiment 1

Neither hormones nor urine was administered to eight hypophysectomised weanlings. Four were killed on the 5th postoperative day and four on the 10th. Of the forty-five mammary glands examined all showed obvious atrophic changes, which were already present by the 5th day (fig. 2, row 2.)

Conclusion.—The mammary glands of the weanling male mouse are totally hormone dependent.

Experiment 2

Œstrone and progesterone were administered to eight hypophysectomised weanlings. In four of these a dose giving an optimal response in the intact animal was injected—i.e., œstrone 0·25 γ and progesterone 1·5 mg. per day per mouse for 5 days. In the remaining four animals this dose was doubled. Forty-four mammary glands were examined, and no sign of a growth response was seen in any.

Conclusion.—The ovarian hormones œstrone and progesterone, at dose levels which produce a vigorous mammary response in intact Strong A_2G weanlings are powerless to induce any proliferation of mammary epithelium in the hypophysectomised weanling males of this strain.

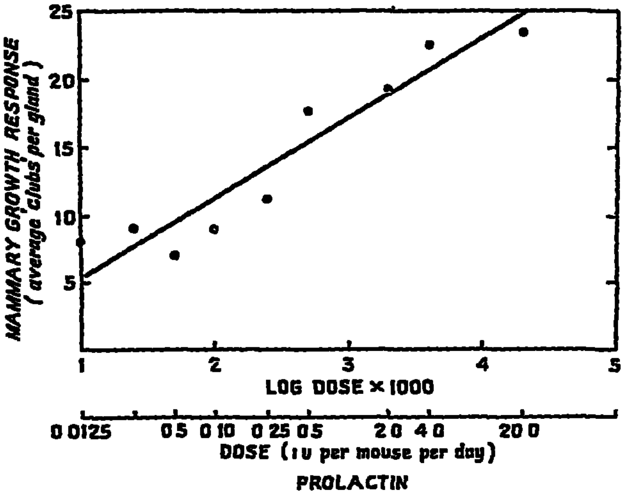

Fig. 1—Dose response curve of mammary growth induced by prolactin (0·0125 to 20 i.u. per day per mouse for five days) in synergism with œstrone and progesterone at constant dose levels.

Experiment 3

Prolactin alone at a dose level which vigorously stimulates mammary growth in the intact weanling (20 international units per day per mouse for 5 days) was administered to five hypophysectomised weanlings. Twenty-three glands were examined. No mammary growth response was seen and in most of the glands there were obvious signs of glandular atrophy.

Conclusion.—Pituitary prolactin alone is not only powerless to stimulate mammary growth in the hypophysectomised weanling male mouse but is incapable of preventing mammary atrophy.

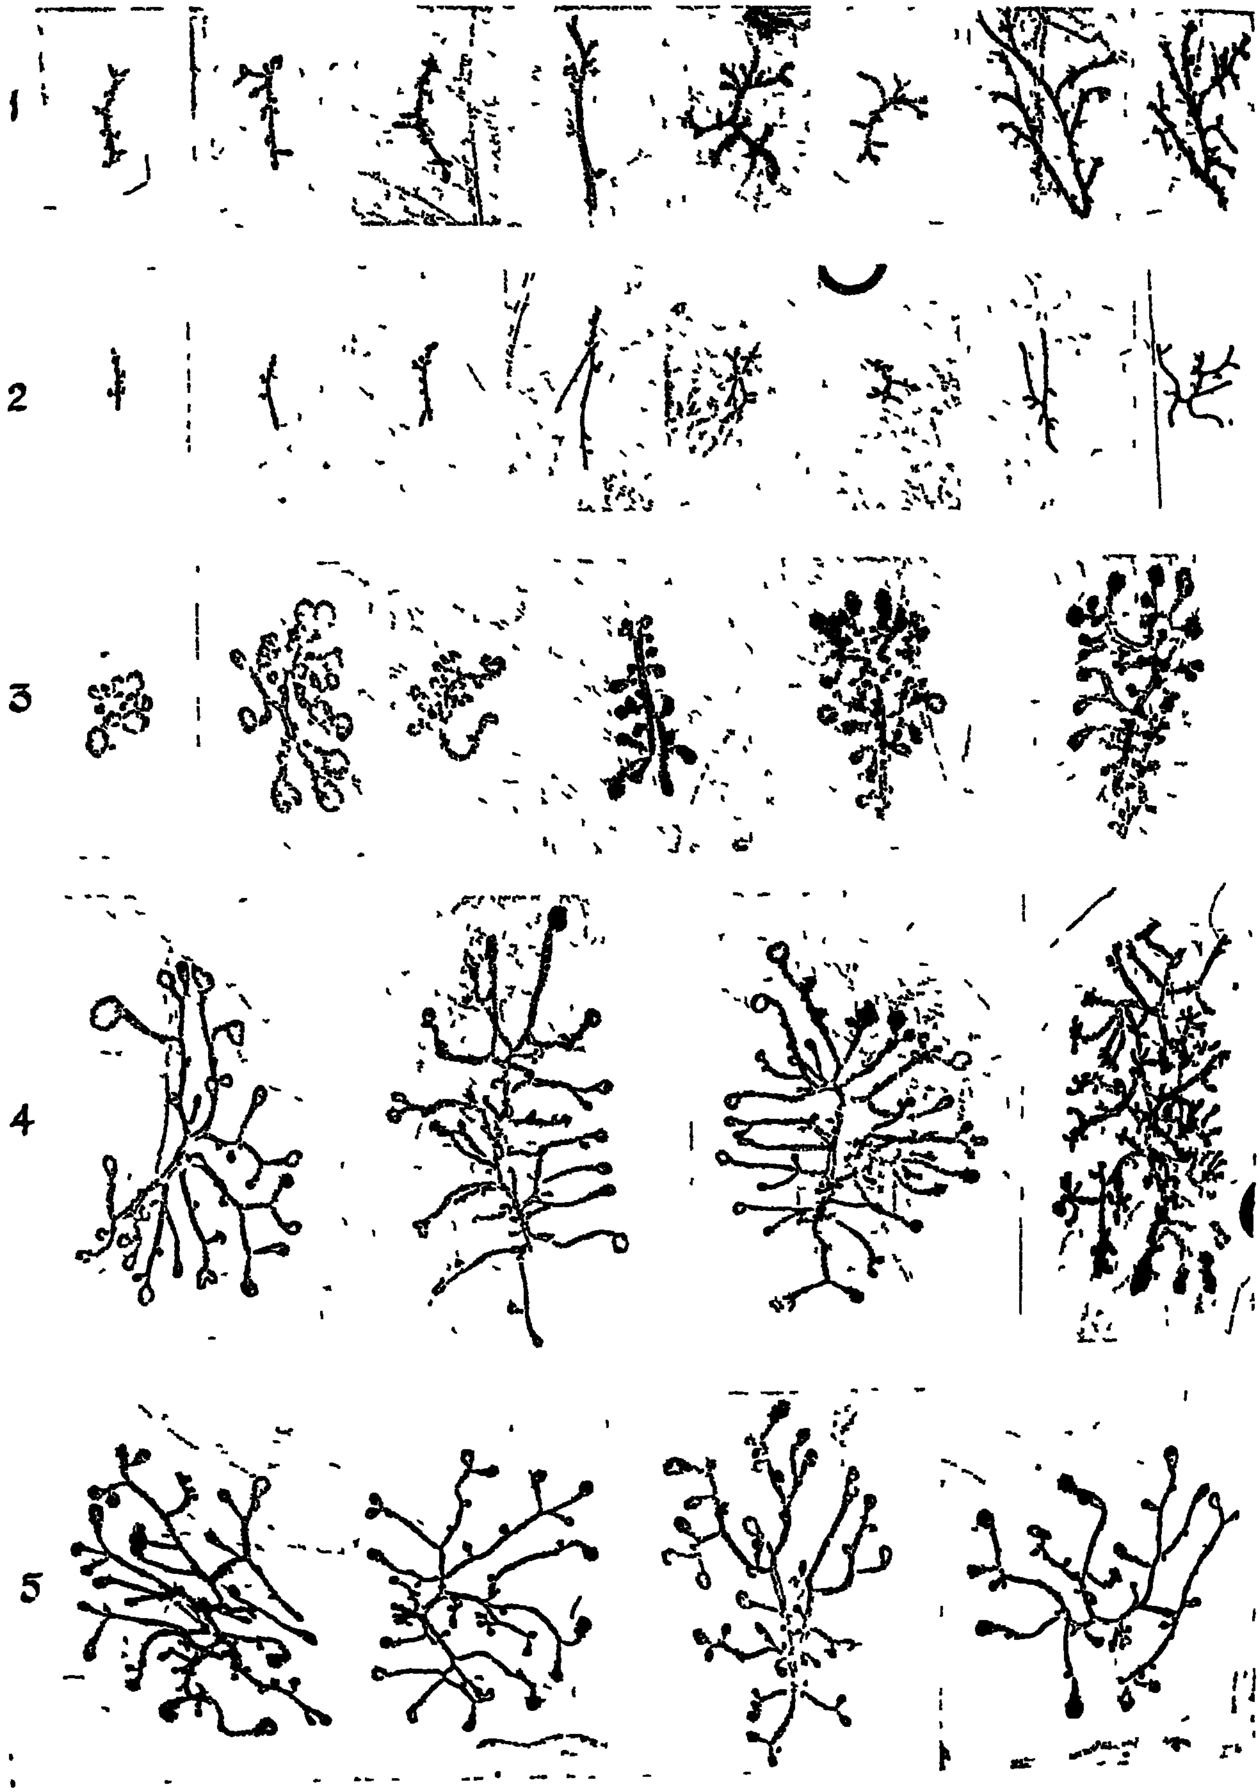
Experiment 4

Œstrone and progesterone together with pituitary prolactin was administered to forty hypophysectomised A_2G weanlings. The dose of prolactin varied from 0·0125 i.u. to 20 i.u. per mouse per day for five days. The dose of ovarian hormones was kept constant at 0·25 γ œstrone and 0·5 mg. progesterone per mouse per day. Two hundred and twenty-eight mammæ were examined. This combination of hormones had induced a vigorous response at all dose levels in all mammary glands in the large majority of animals (fig. 2, rows 3 and 4), and at least 20% of all reacting glands showed early glandular differentiation. The dose response curve is shown in fig. 1.

Conclusion.—The triad of hormones—œstrone, progesterone, and prolactin—is essential for epithelial proliferation and differentiation in the rudimentary mammary glands of the male weanlings of the Strong A_2G strain. As the prolactin used was in all probability contaminated by growth hormone, it is possible that this hormone played a part in the induction of the response, but this seems improbable, for a substantial response was obtained in the mammæ of five animals at the lowest dose level of prolactin (0·0125 i.u. per day per mouse) when the amount of contaminating growth hormone was probably below its threshold value. Furthermore, in none of these animals was there any increase in weight at the 10th postoperative day.

Experiment 5

Pituitary prolactin was omitted from the combination used in experiment 4, and untreated female urines or urinary extract was substituted for it. Œstrone and progesterone were given at the same dose level as in the



1
2
3

5

preceding experiment Twenty-three hypophysectomised weanlings were used

Group 1—Five animals given 0 2 ml per day per mouse for 5 days of an unextracted early-morning specimen of urine from a normal premenopausal woman collected on the 20th day of the menstrual cycle

Group 2—Four animals given the same dose of a pooled specimen from three women at the 21st, 22nd, and 25th days of the menstrual cycle

Group 3—Four animals given the same dose of a pooled specimen of postpartum urines collected on the 3rd, 4th, and 5th postpartum days

Group 4—Five animals given a urine extract prepared by a modification of the Lyons method (1934) from 1455 ml of pooled specimens of early morning urine from a normal premenopausal woman collected on the 15th, 16th, 21st, and 27th days of the menstrual cycle The solution of this extract in normal saline represented a concentration five times greater than in urine

Group 5—Five animals given a urine extract prepared by a modification of the Lyons method (1934) from pooled early-morning specimens of urine collected from eight premenopausal women on the 16th, 19th 20th, 21st, 22nd, 23rd, and 24th (2) days of the menstrual cycle The solution of the dried extract in normal saline represented a concentration five times greater than in urine

A hundred and twenty-three mammary glands were examined An unequivocal mammary growth response, indistinguishable from that produced in experiment 4 by the mammogenic triad, was induced by all specimens of urine acting in synergism with œstrone and progesterone (fig 2, row 5) In the following table the mammotrophic potency of the urine in each group is shown with the approximate amount of prolactin in international units which was found requisite in experiment 4 to induce a mammary response of approximately equal intensity (see fig 1)

Group	Mammotrophic potency of urine or extract (average no of clubs per gland)	Approximate equivalent of prolactin in unextracted urine (I U per mouse per day)
1	6	0 016
2	3 5	< 0 01
3	5	0 01
4 (extract)	17 7	1 225
5 (extract)	8	0 04

Conclusion—The urine of premenopausal women can effectively substitute for the prolactin component of the mammogenic triad and induce significant mammary growth responses in the hypophysectomised male weanling mouse It is highly improbable that growth hormone plays more than an insignificant part in this reaction

Discussion

In many ways the weanling male mouse has proved to be an ideal biological test object for the investigation of mammogenesis induced by exogenous stimulation The experiments reported in this paper, using the hypophysectomised male weanling, implicate pituitary prolactin with a considerable degree of certainty as the mammotrophin present in human female urine Further investigation is clearly needed to decide if human urine contains any significant quantity of growth hormone Some of the results obtained by Lyons and his colleagues (1955) suggest that growth hormone plays a part in developing the duct system of the rudimentary mamma of the hypophysectomised immature rat It is abundantly clear, however, that no combination of hormones which does not include prolactin can bring this rudimentary gland to anything approaching the status of a functionally competent organ There is no doubt that many specimens of easily available growth hormone are contaminated by prolactin, and, unless very elaborate precautions are taken in their preparation, many commercial preparations of prolactin contain growth hormone in small and possibly insignificant amounts It seems safe to assume, therefore, that in some of the mammary reactions described in this paper growth hormone may have played a subsidiary part

Certainly the hypophysectomised mouse is far more sensitive to exogenous prolactin and human urine than the intact animal, and yields more uniform mammary reactions

It will be necessary to define the nature of the genetic peculiarity in Strong A_2G mice which endows the male weanlings of this strain with their exceptional mammary reactivity to prolactin and human urine Experiments now nearing completion have shown that the ratio

$$\frac{\text{Testis weight}}{\text{Body weight}}$$

is significantly higher in these animals than in the male weanlings of prolactin insensitive strains

If, as a measure of pituitary mammotrophic function, the mouse test proves to be of clinical value in rationalising the treatment of breast cancer by hypophysectomy the difficulties associated with strain variation could be met by establishing colonies of Strong A_2G mice in centres where hypophysectomy for breast cancer is under investigation

General Conclusions

1 Experimental evidence is produced supporting the conclusion that human female urine contains pituitary prolactin at concentrations varying from 0 01 to 0 25 international units per millilitre

2 It is suggested that an estimation of urinary prolactin may materially assist in the selection of those patients with metastatic breast cancer who are likely to benefit from hypophysectomy

3 It is also suggested that, for the bio-assay of prolactin in human urine, potent urinary extracts (which can be preserved indefinitely) should be injected into hypophysectomised male weanling mice of the Strong A_2G strain

My warmest thanks are due to Dr O Muhlbock director of the Netherlands Cancer Institute, Amsterdam, for kindly providing facilities for me to learn the technique of hypophysectomy in the mouse and it gives me much pleasure to express my gratitude to Dr Kwa Hong Giok, of the same institute for his invaluable advice, encouragement and assistance during the investigations

The urinary extracts were prepared by my colleague Dr F C Greenwood, his assistance has been invaluable I am grateful to Dr W F J Cuthbertson for arranging supplies of mice from the Glaxo Laboratories, and to Messrs Armour who kindly gave me the prolactin

MUMPS VIRUS AND SUBACUTE THYROIDITIS

EVIDENCE OF A CAUSAL ASSOCIATION

E Eylan
M D , Ph D

R Zmucky

OF THE A [illegible] LABORATORIES FOR PUBLIC HEALTH, TEL AVIV

Ch Sheba
M D

OF THE TEL HASHOMER HOSPITAL, ISRAEL

Subacute thyroiditis has distinctive clinical and pathological features, it can be clearly differentiated on the one hand from acute pyogenic infections of the thyroid, and on the other, from the forms of chronic thyroiditis described by Riedel and by Hashimoto Its cause is unknown, but the clinical and pathological features are generally admitted to be compatible with infection by an as yet unidentified virus

Subacute thyroiditis is regarded as rare, but a comparatively large number of cases has been seen in Israel in recent years This has provided an opportunity for a renewed search for evidence of a causal virus 14 female patients and 1 male with subacute thyroiditis have been studied from this point of view

Clinical Features

The illness usually started with mild pyrexia, accompanied by pain radiating from the neck to the ears, particularly noticeable on swallowing Swelling and tenderness of the thyroid gland, either bilateral or unilateral, appeared a few days later Tachycardia, sweating, and tendency for the eyes to stare were often seen A few patients complained of abdominal discomfort, but no abnormal physical signs were found

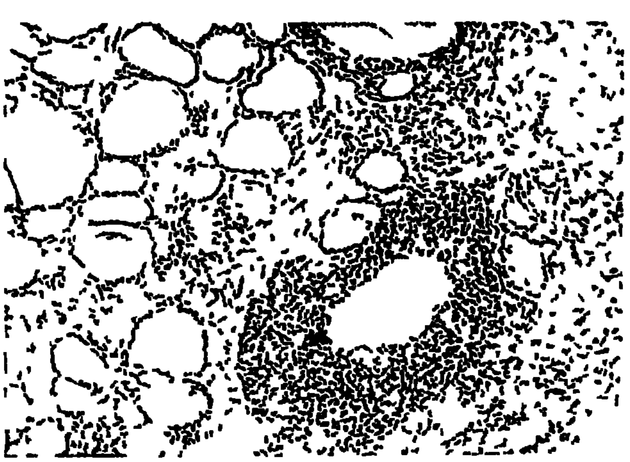

Fig 1—Subacute thyroiditis showing polymorph infiltration round colloid follicle (Hæmatoxylin and eosin × 75)

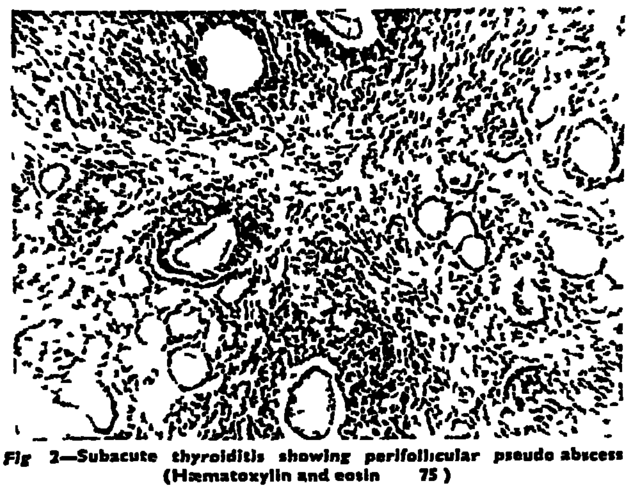

Fig 2—Subacute thyroiditis showing perifollicular pseudo abscess (Hæmatoxylin and eosin × 75)

In our material the progress of the disease was not left to its natural course, in 11 out of 15 cases corticotrophin or cortisone was administered The swelling of the thyroid gland disappeared within seventy two hours after the start of such treatment The pyrexia usually disappeared within twenty four hours In 7 of these cases the pyrexia and painful swelling of the gland recurred after the end of steroid medication In none of our cases was a lasting swelling or myxœdema recorded

10 patients were studied by two of our staff (Dr Harell Steinberg and Dr P Cerniak) for a long time with repeated ^{131}I and protein bound iodine (P B I) studies, and, after six months at most, all reverted to euthyroidism, none later developed either permanent hypothyroidism as reported by Keating et al (1950) or hyperthyroidism as reported by others

Investigations

A mild polymorph leucocytosis (up to 17,000 per c mm) was observed in three quarters of the cases The erythrocyte sedimentation rate was usually raised—above 50 mm in 1 hour (Westergren) in 11 of 15 cases The serum P B I level was above 8 µg per 100 ml in 8 of 11 cases in which it was estimated In contrast the uptake of radio iodine was greatly reduced in 12 of 15 cases The combination of a high P B I and low radio iodine uptake is regarded by most observers as characteristic of subacute thyroiditis

Histology

Biopsy was performed in 4 cases Invasion by inflammatory cells was present in all In 2 cases investigated early in the disease polymorphonuclear cells predominated but lymphocytes predominated in the 2 later cases There was gross disruption of the normal acinar pattern in all 4 cases Giant cells were often seen, probably representing the remains of acini which had been destroyed (figs 1–3)

Complement fixation Tests against Mumps Virus

Complement-fixation tests were performed by the method of Kolmer and Boerner (1941) using Lederle viral antigen

The results are shown in table I Positive results were obtained in 10 of the 11 cases In the 1 negative case (case 4) the histology of the thyroid was atypical

Table II shows the results of the complement fixation tests done long after clinical recovery The tests probably become negative some eight to ten months after the onset

Since a very large proportion of the population has had mumps at one time or another, it was necessary

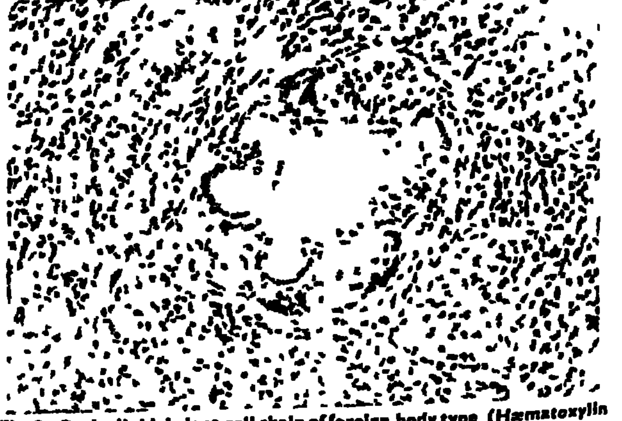

Fig 3—Pericolloidal giant cell chain of foreign body type (Hæmatoxylin and eosin × 150)

to examine numerous controls Of 52 healthy women, aged 30–64, the complement-fixation tests were negative to mumps in 42, and positive in 6 to a titre of 1 10 and in 4 to a titre of 1 20

A further possibility was that the positive complement fixation tests in subacute thyroiditis represented an anamnestic response in persons previously in contact with mumps virus Patients with various diseases, including acute fevers, were therefore studied, with the results shown in table III

From these control studies we concluded that positive complement-fixation tests to a titre of 1 80 or more could be taken as evidence of recent contact with mumps virus

Isolation of a Virus

Attempts to recover a virus from blood and fæces were unsuccessful

In 2 cases in which biopsy was done a virus was recovered from the excised thyroid gland (cases 1 and 3) The specimens were inoculated intracerebrally into mice and hamsters (newborn and adult) and into the yolk-sacs of 8 day fertilised eggs

The results of animal inoculation were negative except in the case of the baby hamsters In a proportion of these animals signs of encephalitis appeared six to nine days after inoculation of the specimens from both patients It proved possible to passage the infective agent by intracerebral injection into further baby hamsters, both with and without Seitz filtration

TABLE I—COMPLEMENT-FIXATION TESTS AGAINST MUMPS VIRUS IN SUBACUTE THYROIDITIS

Case no	Age (yr)	Day of illness	Titre
1	42	6 24 45 128	1 40 1 160 1 160 1 160
2	62	7 22 62	1 40 1 160 1 160
3	30	33 53	1 160 1 40
4	54	6 13 96	Negative Negative Negative
5	24	9 22 223	1 40 1 160 1 80
6	24	9 22	1 80 1 80
7	,3	6 20 53	1 80 1 80 1 40
8	42	4	1 80
9	41	14	1 160
10	38	8 18	1 40 1 160
11	13	30 45	1 80 1 80

Yolk sacs were emulsified five days after inoculation and injected into the amniotic sac of 8 day fertilised eggs After a further five days amniotic fluid was removed and found to agglutinate human group O red cells Hæmagglutination was suppressed by the addition of serum from patients convalescent from classical mumps, and by serum from patients with subacute thyroiditis Serum from healthy female controls did not suppress hæmagglutination or only to an insignificant degree

Discussion

The positive complement fixation tests obtained in 10 of 11 patients with subacute thyroiditis provide evidence of recent contact with mumps virus Isolation of a virus from two affected thyroid glands strongly suggests that it was the cause of the observed pathological changes Specific inhibition of hæmagglutination by convalescent mumps serum establishes the identity of the virus

TABLE II—COMPLEMENT FIXATION TESTS IN PATIENTS AFTER RECOVERY

Case no	Age (yr)	Titre during illness	Interval (months)	Titre after recovery
12	40	Not tested	17	Negative

Total	35	31 negative 4 positive 1 20

The hypothesis that the cases of subacute thyroiditis observed during the present outbreak in Israel were caused by infection with mumps virus is quite compatible with the known clinical and epidemiological facts This virus has a predilection for glandular tissue (salivary, pancreatic, lacrimal, testicular, mammary, and ovarian) Although concomitant enlargement of salivary and thyroid glands was not observed in our cases, abdominal pains were not uncommon, and in 3 of 6 cases in which it was looked for a rise in blood-diastase above 200 Somogyi units was observed

During the period when our cases of subacute thyroiditis were discovered the incidence of mumps was particularly high in Israel, the rate per 10,000 having risen from 12 in 1953 to 32 and 44 in 1955 and 1956 In the earlier cases studied a history of contact with mumps was not inquired for, because the possibility of this association had not then occurred to us Of the later cases, 4 had been in close recent contact with cases of classical mumps

In putting forward the suggestion that mumps virus may be the cause of subacute thyroiditis it is important to emphasise that our findings apply only to the local outbreak of this disease in Israel It is quite possible that different ætiological agents are concerned in different places and at different times

Summary

An unusually large number of cases of subacute thyroiditis has been seen in Israel in the past two years The clinical and pathological features of these cases are described

10 of 11 cases had positive complement-fixation tests against mumps virus to a significant titre

A virus thought to be identical with mumps virus was isolated from the thyroid glands of 2 patients with subacute thyroiditis

It is suggested that mumps virus was the cause of the thyroiditis in these patients

BENIGN GASTRIC ULCER

RISK OF COMPLICATION IN RELATION TO SITE

Eddy D Palmer
M D Rochester
LIEUT COLONEL, MEDICAL CORPS, U S ARMY
From the Medical Service, 2nd U S Army General Hospital, Landstuhl/Pfalz, Germany

THE complication-rate of benign gastric ulcers including those which are under treatment, is high, and the complications of gastric ulcer are less predictable than those of duodenal ulcer Although few surgeons now believe that all gastric ulcers should be cut out because they might be cancerous, gastrectomy remains good treatment for certain benign ulcers Whether it is advisable depends largely on a history of complications in the past and a guess as to their likelihood in the future

To determine the risk of complications of ulcers in various parts of the stomach, I have reviewed the records of 250 personally observed patients with gastric ulcer The ages of the patients at the time of diagnosis ranged from 16 to 88, 62% being between 20 and 50 The diagnosis was established rontgenologically in 245, gastroscopically in 238, and by operation or necropsy in 84 12 patients had two ulcers, 5 had three, and 4 had five, making a total of 288 ulcers The average length of ulcer illness covered by this report was 45 1 months, and the average length of controlled therapy 16 4 months 38 of the patients first came to medical attention because of a complication, therefore, there was a misleading concentration of complications during the observation period

Among 109 patients there were 115 complications (see table), 6 patients having both hæmorrhage and perforation (In view of the high rate of complications observed, it is interesting that double complications were no commoner) There were totals of 77 instances of hæmorrhage, 18 of perforation, 10 of penetration and 10 of obstruction 4 of the penetrations involved the pancreas, 4 the lesser omentum, and 2 the liver

The proportion of ulcers giving rise to complications was highest in the distal part of the stomach and lowest in the proximal, decreasing progressively (53% in the pylorus, 42% in the antrum, 37% in the pars media, and 28% in the cardia and fundus) Also it was found that ulcers of the anterior wall—omitting pyloric ulcers—were far more prone to complication (63%) than those of the lesser curvature (37%), posterior wall (35%), or greater curvature (33%)

Analysis according to the type of complication shows that, with one or two exceptions, apparently governed by the small numbers of cases represented, the risk of hæmorrhage was approximately the same for ulcers in all parts of the stomach Perforation, on the other hand, was far commoner among anterior-wall ulcers, and (surprisingly enough) only 20% of the cases of penetration involved posterior wall ulcers Obstruction, as one might expect, was always caused by distal ulcers, except in one case where constriction across the pars media produced enough hour glass constriction to obstruct

ASTHMATIC WHEEZING

COMPRESSION OF THE TRACHEA AND MAJOR BRONCHI AS A CAUSE

E Dekker
M D Amsterdam

J Groen
M D Amsterdam

From the Second Medical Service of the Wilhelmina Gasthuis, Amsterdam

IT is commonly assumed that the typical wheezing during the expiratory phase of the asthmatic attack is produced by a stenosis of the smaller bronchi and bronchioli Opinions differ about the cause of this stenosis Some attribute it to spasm of the bronchial and bronchiolar musculature, others to a partial obstruction by mucus, or œdema and congestion of the bronchial mucosa, or both In this paper we present evidence for another explanation of asthmatic wheezing —namely, that it may be produced, at least partly, by a narrowing of the trachea and larger bronchi

We have already described how typical asthmatic attacks were produced and reproduced under controlled laboratory conditions by exposing patients to allergic or emotional stimuli (Dekker and Groen 1956) These experimentally provoked attacks could begin so suddenly that doubt was cast on the common assumption that spasm in smooth muscle or secretion of mucus were responsible A similarly sudden onset and disappearance of the wheeze is commonly seen in clinical practice—e g , when a patient relates his history This made us doubt the validity of the hypothesis that the wheezing is produced by a mechanism involving the autonomic nervous system, and led us to seek another explanation

Talma (1898a and b) and Strübing (1906) emphasised two points that seem to have been overlooked by most modern authors

(1) The sound heard is exactly identical when the stethoscope is applied to different places on both sides of the thorax and over the trachea This must mean that the typical wheezing is not produced by multiple local stenoses of the smaller air-passages but by a centrally situated narrowing of the trachea or of the major bronchi, whence it is conducted over the entire thorax This narrowing was indeed observed by Van Hoek (cited by Talma 1898a and b), an assistant of Zwaardemaker, and later by Talma (1898a and b) himself through the laryngoscope

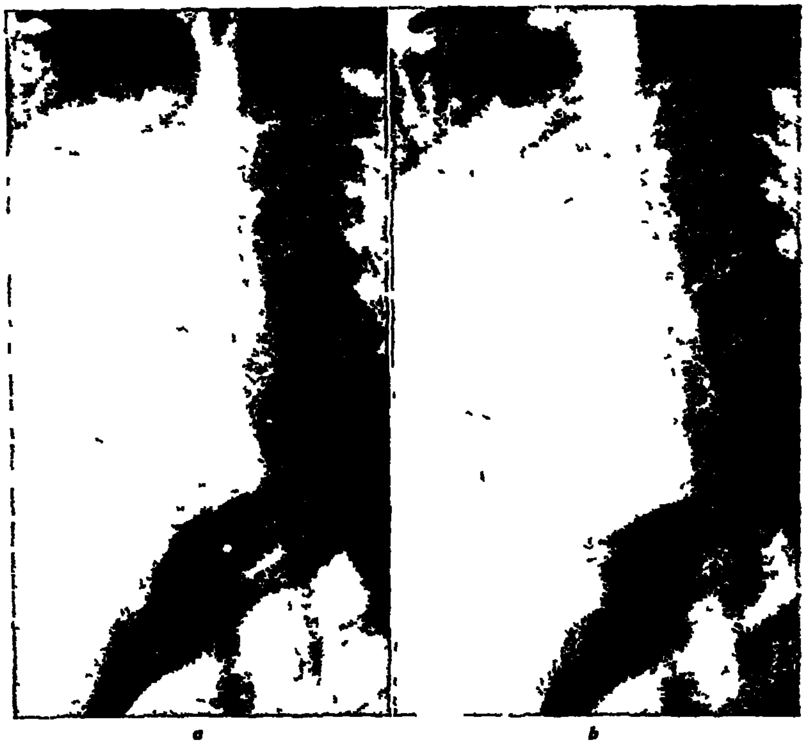
(2) Many asthmatics, when asked to demonstrate " how it wheezes " during an attack can produce audible wheezing at will Normal people can also learn to do this This suggests that the wheezing (i e , the stenosis of the upper respiratory passages) can be produced by a *voluntary* effort

Following this line of thought, we have asked ourselves whether this voluntary effort could be mediated through the positive pressure created in the thorax by the powerful contraction of the abdominal, thoracic, and cervical musculature during the typical " asthmatic " expiration During such an expiration the contents of the thorax are compressed by a pressure which is many times higher than normal and high enough to narrow the trachea and the larger bronchi to a considerable degree In the trachea and main bronchi this compression is chiefly caused by the membranaceous part of the wall being pressed into the lumen This has already been suggested, though in somewhat different terms

(Biermer 1870, Einthoven 1892, Sahli 1920) It has been clearly observed by many investigators through the bronchoscope (Von Schrotter 1906, Brünings 1910, Keiper 1914, Lukens 1925, Moore 1925, Daily and Daily 1929, Clerf 1935, Van Loon and Diamond 1942, Leli 1946, Lemoine 1949, Waldbott 1949, Turiaf et al 1952, Lemoine and Garaix 1953, Herzog 1954, Howell 1955, Wyss 1955) and by other authors by bronchography (Di Rienzo 1949a and b, 1953, Stutz 1952, Van Exter 1953), but the possibility that the compression could be the origin of the wheeze, and contribute to the dyspnœa, has not received the attention it deserves

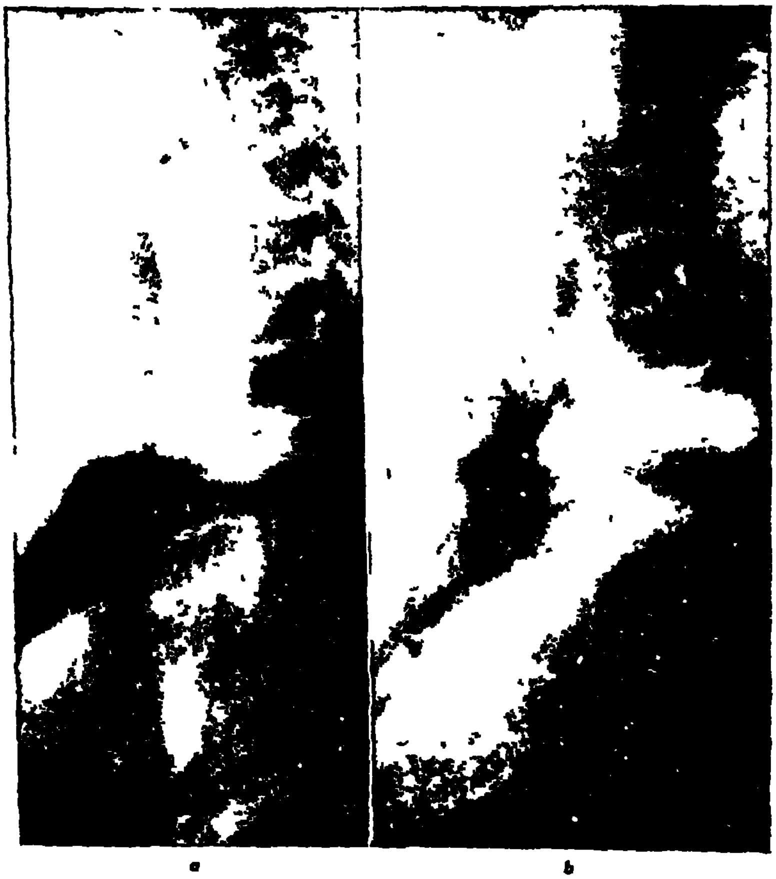
Investigations in Vivo

Healthy people and asthmatic patients were taught to "wheeze" We followed the method indicated by Strübing (1906) to teach wheezing After a short inspiration, a short cough is followed by a prolonged forceful "pressing" expiration Gradually the closure of the glottis, preceding the cough, is omitted and the pressing expirations continued The best results are obtained when the investigator first learns to wheeze himself, and then demonstrates the technique to the subjects Of 17 healthy subjects in whom we tried this manœuvre, 15 were able to imitate the wheeze after a few trials In some of them the resemblance between this artificially induced wheezing and the spontaneous wheeze during the asthmatic attack was most striking Asthma patients similarly learned to wheeze at will and in them the resemblance to the spontaneous wheeze was even more obvious



a b

Fig 2—Radiographs of larynx and trachea (asthmatic patient) (a) during inspiration, (b) during voluntary wheezing expiration



a b

Fig 1—Radiographs of larynx and trachea (normal subject) (a) during inspiration (b) during voluntary wheezing expiration

The second part of the investigations was radiological Frontal, transverse, and oblique short time exposures were made of the dynamic changes in diameter of the trachea and the main bronchi during inspiration and during a voluntary wheezing expiration, in healthy subjects and in asthmatic patients Similar studies were done on asthmatic patients during spontaneous attacks *

Results

During voluntarily induced "asthmatic" expiration in a normal subject, narrowing of the lumen of the trachea was seen to extend into the lower part of the cervical trachea (fig 1) In our opinion this is due to the propagation of positive pressure inside the cone of cervical musculature (on the anteroposterior exposures it could be seen that the glottis was open during voluntary wheezing expiration)

---

* These investigations were carried out in coöperation with Dr R C Ledeboer in the university department of röntgenology under the direction of Prof Dr B G Ziedses des Plantes, they will be published more extensively elsewhere

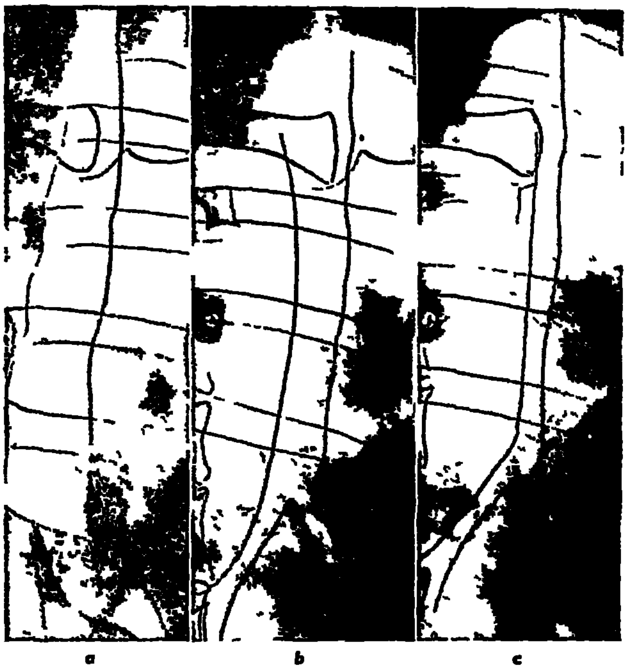


Fig 3—Right oblique radiographs of trachea and main bronchi (emphysematous asthmatic patient) during an attack of dyspnœa (outlines drawn). (*a*) during inspiration; (*b*) during expiration; (*c*) during voluntary wheezing expiration.

An equally considerable narrowing of the main airways was seen during voluntary wheezing expirations in patients with asthma and emphysema (figs 2*b*, 3*c*, 4*c*). The extent and situation of the tracheo bronchial constriction were strikingly similar to those seen in the normal subjects.

Exactly the same type of narrowing of the cervical and thoracic trachea and the major bronchi was found during normal expiration in a patient with emphysema (fig 3*b*) and a patient with asthma (fig 4*b*) during severe spontaneous attacks of dyspnœa.

Experiments in Vitro

The above experiments, together with the demonstration *ad oculos* of the narrowing of the trachea and main bronchi by bronchoscopy and bronchography, do not yet answer the question whether this narrowing is caused by active constriction (e.g., by spasm of the tracheal and bronchial musculature), or is a result of a purely passive compression by the increased thoracic pressure during forceful prolonged expiration. To investigate this we used a human lung obtained at necropsy.† The preparation was put in a glass jar that could be closed by a brass lid. The trachea was tied over a glass cannula that pierced the lid and thus connected the trachea and bronchi with the outside air. By another opening in the lid, air could be pumped in and out of the jar, about 20 times a minute (fig 5). The inspiratory and expiratory pressures of this "respiration" could be varied and measured by a manometer. When the lung "breathed" under a pressure comparable to the physiological pressures in the thorax (i.e., a negative pressure of about 1 cm Hg during inspiration and atmospheric pressure during expiration) a slight widening of the trachea during inspiration was observed but there was no compression during expiration. But when the expiratory pressure inside the jar was increased to 1 cm Hg or more, prolapse of the membranaceous part of the trachea and the main bronchus into the lumen was clearly visible, causing considerable narrowing. This prolapse started early in the expiration (fig 5).

For the study of the "breath sounds" of this preparation, agonal œdema fluid or bronchial exudate were evacuated by suction. When the main air passages were dry, a piece of rubber tubing, attached to a stethoscope was introduced into the tracheal cannula. No wheeze was heard when the lung expired under atmospheric pressure, but when the expiratory pressure in the jar was increased to 2 cm a high pitched wheeze became clearly audible through the stethoscope.

Positive pressures of 1–2 cm Hg (14–27 cm of water) are easily produced in vivo during forced expiration; much higher intrathoracic pressures have been measured directly or through œsophageal catheters during expiration in asthmatic attacks (Dayman 1951, Fry et al 1954, Mead et al 1955, Wyss 1955). Thus a passive compression, comparable to that in these experiments in vitro, may reasonably be supposed to take place in vivo.

In the living subject the posterior wall of the trachea is attached to the anterior wall of the œsophagus, but this does not prevent its being pushed forward during the expiration, as shown by the aforementioned observations. In fact, physiological experiments (Buytendijk 1949) have shown that the walls of the œsophagus behave so passively that the pressure in its lumen can reliably be used for the determination of intrathoracic pressure.

Discussion

These investigations seem to support the hypothesis that high intrathoracic pressure (produced by asthmatic patients during the peculiar *forceful expiration* which is part of the characteristic breathing pattern in this disease) causes a passive compression in the larger air passages which will lead to increased air flow resistance and should seriously be considered as a cause of asthmatic wheezing.

Our observations as yet do not indicate how far down into the intrapulmonary airways this compression

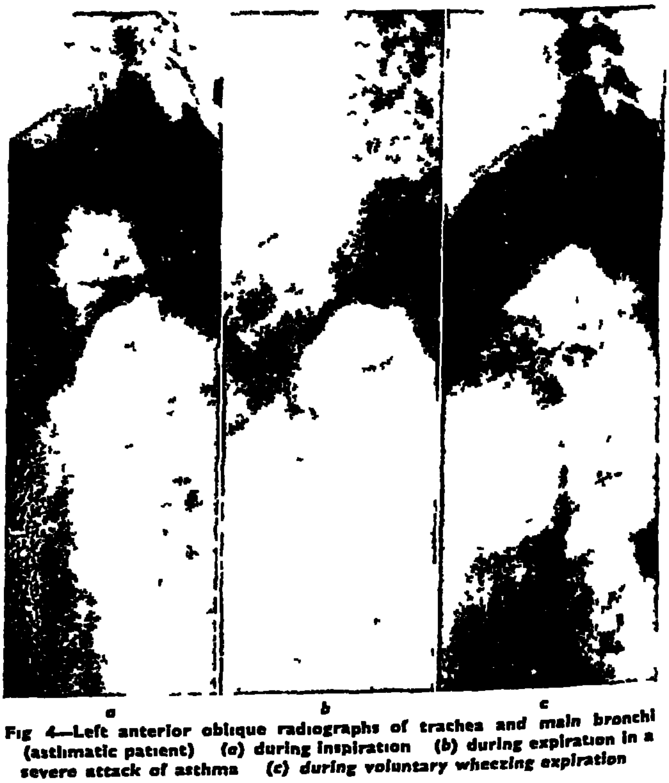

Fig 4—Left anterior oblique radiographs of trachea and main bronchi (asthmatic patient). (*a*) during inspiration; (*b*) during expiration in a severe attack of asthma; (*c*) during voluntary wheezing expiration.

---

† We are indebted to Prof Dr H T Deelman and his staff for providing us with this material.

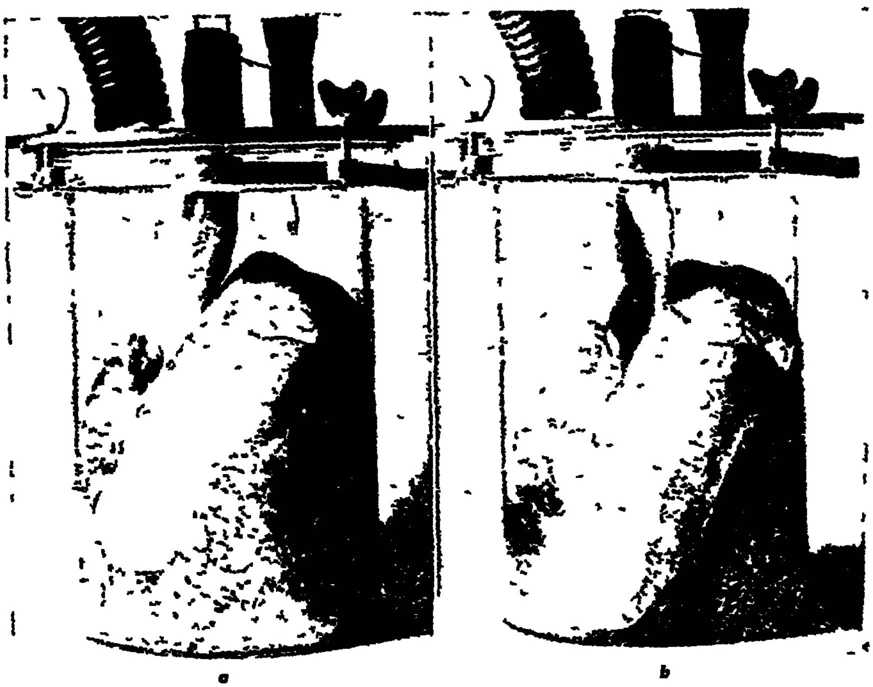

Fig 5—Isolated human lung, "breathing" in a closed jar. (a) mid inspiration, trachea wide open; (b) mid expiration under positive pressure (2 cm Hg), trachea narrowed by impression of posterior wall into lumen.

extends. It is obvious that the high intrathoracic pressure during expiration compresses not only the trachea and major bronchi but also the intrapulmonary air passages, because the intrathoracic pressure is transmitted through the pulmonary tissue. At least three forces, however, oppose this compression:

(1) The rigidity of the walls of the bronchi and bronchioli.

(2) The centrifugal dilating forces of the pulmonary tissue, depending on the state of inflation of the lung (Sonne 1923, Von Neergaard and Wirz 1927, Huizinga 1938, Stutz 1949, Van Exter 1953).

(3) The intraluminal air pressure in the bronchi.

The rigidity of the tracheo-bronchial tree is commonly overestimated. This has led some to assume that the so-called check-valve mechanism is localised only or predominantly in the unsupported bronchioles (Dayman 1951, Fry et al 1954). Others have been so impressed by the tracheo-bronchial collapse observed either through the bronchoscope (Lemoine 1949, Lemoine and Garaix 1953, Herzog 1954) or by radiology (Pohl 1951, Herzog 1954), that abnormal flexibility of the walls was held to be the primary cause of the phenomenon. Even a plastic operation has been developed for this condition (Nissen 1954). But in those cases where abnormal laxity of the walls really existed the sequence of events might well be reversed. Abnormal flexibility might result from the continuous overstressing of the elastic elements in the walls during the continuous compression with each expiration.

Emphysema will lead to loss of the centrifugally dilating forces (Dayman 1951, Fry et al 1954), thus facilitating the compression.

The intrabronchial pressure in the cartilage supported airways would be decreased by any stenosis in the small peripheral bronchi. This might be caused by mucus, congestion of the mucous membrane, or increased muscle tone. Decreased intraluminal pressure in the bronchi leaves the compressing forces unbalanced. Thus bronchiolar stenosis contributes to the expiratory compression of the larger airways. A primary increase of peripheral resistance, however, is not indispensable for the wheezing by passive compression, as is shown by our experiments with normal individuals.

On the other hand, any increased resistance downstream will increase the intraluminal air pressure, thus supporting the walls. Barach and Swenson (1939) emphasised the importance of this mechanism in positive pressure breathing and pursed-lip breathing in the treatment of patients with asthma and emphysema. We can confirm their observation that pursed-lip breathing may momentarily stop the wheeze in these patients.

There is as yet insufficient evidence for a statement on the relative importance of the contribution of the cartilage supported air-ways and the bronchioles in the production of asthmatic wheezing. Some of the finer wheezing heard over the thorax through the stethoscope may originate in the bronchioles, but we feel that the majority of wheezing sounds which can be heard from the patient's mouth at a distance are produced in the larger, cartilage supported, airways. Tubes with a bore of less than 1 mm are poor conductors of sound, especially in the higher frequency ranges (Martini and Müller 1924, Rappaport and Sprague 1951). On the other hand, it is common experience to bronchoscopists that a foreign body in the larger airways produces wheezing indistinguishable from asthmatic wheezing (Jackson 1921, Clerf 1935, Lell 1946).

The influence of the "voluntary" respiration muscles on the diameter, flow resistance, and wheezing of the cartilage supported airways opens interesting possibilities for the explanation of increased outflow resistance (Von Neergaard and Wirz 1927, Dayman 1951, Fry et al 1954, Wyss 1955), the pathways of emotional influences (Groen and Bastiaans 1953, Bastiaans and Groen 1955, Dekker and Groen 1956), and the results of breathing and posture exercises (Saenger 1904, Heckscher 1936, Howell 1955) in asthma.

Summary

We have confirmed old observations that asthmatic patients and normal people can learn to wheeze at will by imitating the typical asthmatic expiration. This voluntarily produced wheezing is indistinguishable from the spontaneous wheezing during asthmatic attacks. X-ray studies during this voluntary wheezing reveal, both in normal subjects and in asthmatic patients, a considerable narrowing of the cervical and thoracic trachea and of the main bronchi. The same narrowing was found in X-ray pictures taken during the expiration in patients with spontaneous asthmatic attacks. In human lungs, obtained at necropsy, which were made to breathe under different pressures in a closed jar, an expiratory pressure of 1 cm Hg or more produced a considerable stenosis by a prolapse of the membranaceous part of the trachea and main bronchi into the lumen. It is postulated that a similar passive compression of the larger air passages, caused by the high intrathoracic expiratory pressure which asthmatic patients produce as a result of their peculiar type of breathing, is an important factor in the production of the asthmatic bronchostenosis and of the expiratory wheezing which is so characteristic of this disease. The importance is

noted of these observations for understanding the mechanisms by which asthmatic attacks are brought about and by which they can disappear with breathing exercises

A METHOD OF MEASURING THE pH OF BODY-FLUIDS

VICTOR WYNN
M D Melb
SENIOR LECTURER IN SURGERY

JOHN LUDBROOK
M B B Med Sc N Z *
RESEARCH ASSISTANT, SURGICAL UNIT

ST MARY'S HOSPITAL, LONDON

THE method described here is especially suitable for measuring the pH of small amounts (about 0 5 ml) of blood The apparatus is simple to use and to maintain and is designed for continuous operation , so there is a delay of only about 5 minutes between blood reaching the laboratory and the measurement of its pH The standard deviation for the reproducibility of pH measurement of blood is 0 005 pH units, which is well within the limits necessary for clinical work

Apparatus

Constant temperature pH Cell (fig 1)

A is the glass electrode with a bulb type membrane and ground glass cone (size B7) fitting into the socket in the neck of the anaerobic chamber (B) The chamber is of 0 4 ml capacity and leads by a capillary about 0 5 mm in diameter to a hollow-key one-way stopcock (C) The barrel of the stopcock has a glass back to prevent fluid and electrical leakage The hollow key is pierced at either end to allow air to escape when the key is inserted into the barrel A little petroleum jelly is applied to the wide end of the key and to the narrow end of the barrel Thus, when the key is inserted into the barrel and rotated, a layer of grease is formed at each end of the stopcock, leaving a clear ring between, around which the KCl forms a conducting path Silicone grease should not be used, because it may interrupt the conducting path The lower opening of the stopcock leads to the reservoir (D) containing 3 5 *M* KCl and the calomel half cell (E), which is of the conventional 3 5 *M* KCl type Glass collars are fused to the top of the vessels containing the glass and calomel electrodes to provide a moat between them and the water bath This moat is kept clean and dry to prevent electrical leakage

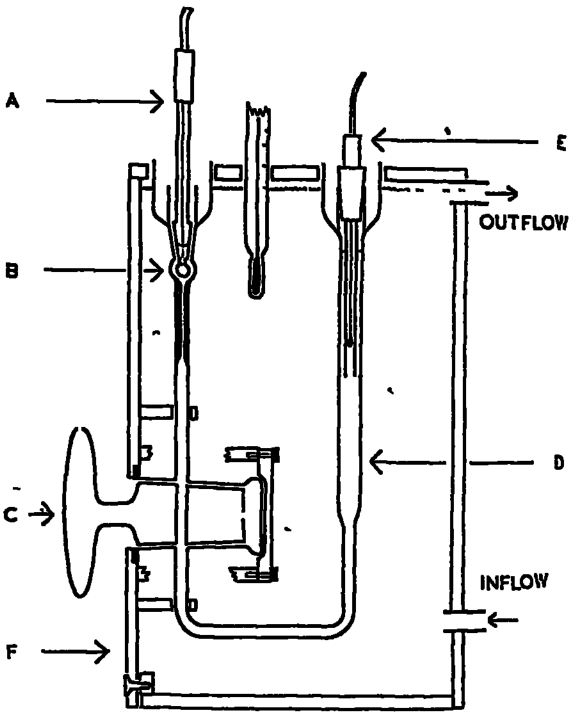

Fig 1—Constant-temperature pH cell A, glass electrode , B, anaerobic chamber , C, stopcock , D, reservoir for 3 5 M KCl , E, calomel electrode , F, perspex box with removable front Inflow and outflow ducts are connected to recirculating pump and thermostatically controlled water-bath

The whole of this glassware is fitted to the detachable front of a ' Perspex ' box (F) The box is surrounded by electrostatic shielding and contains water maintained at 38 0 ± 0 1°C by a thermostatically controlled reservoir water bath and a recirculating pump capable of exchanging the volume of the box every 2 minutes

A thermometer, whose bulb is near the glass electrode chamber, is graduated in tenths of a degree C There is a duplicate chamber to B connected to a distilled water reservoir, in which the glass electrode is stored at 38°C ready for use

Glass Electrode

This consists of a thin bulb of MacInnes Dole glass fused to the stem just below the ground glass cone It is of the standard Ag/AgCl/0 1*M* HCl type with shielded input lead It is mechanically robust and, in our experience, gives constant response for at least nine months

Measuring Apparatus

This is a direct reading millivoltmeter based upon the dynamic capacitor with full scale deflections of 10, 30,

---

* N Z University Travelling Scholar

100, 300, and 1000 mV The effect of variations in mains voltage is negligible, and the apparatus may be left running continuously In series with the low-resistance input from the calomel electrode is a potentiometer (fig 2) By means of this a steady back E M F is applied which is adjusted to enable the full length of the appropriate scale to be used for the pH determination

Buffer Solutions

The buffers used and the pH values assigned to them are those described by Hitchcock and Taylor (1938) and recommended by the British Standards Institute (specification 1647 1950) These give virtually the same pH scale as that recommended by the U S National Bureau of Standards (L C 993 - 1950) They are 0 05 M potassium hydrogen phthalate (pH 4 025 at 38°C), a mixture containing 0 025 M disodium hydrogen phosphate and 0 025 M potassium dihydrogen phosphate (pH 6 835 at 38°C), and 0 05 M disodium tetraborate decahydrate (pH 9 070 at 38°C) They are easy to make up and, if a crystal of thymol is added, the former two remain stable for at least two months, the latter for a shorter period

The buffers are prepared by dissolving the proper weight of 'Analar' reagent grade salt in reboiled distilled water of pH 6 7–7 3 and making up to one litre in a volumetric flask Before being weighed, the potassium hydrogen phthalate and the phosphate salts are dried in an oven at 110°C for two hours and cooled in a desiccator Disodium tetraborate decahydrate is dried without heating in a desiccator for forty eight hours These buffers have a high buffering capacity and a low dilution effect Buffers of intermediate value to those described here have not these properties, and we have found that commercially made intermediate buffers designed to have a pH nearer to that of blood soon change from their nominal pH values

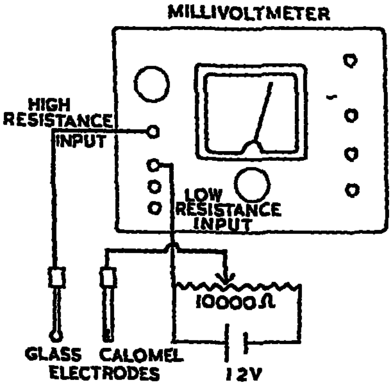

Fig 2—Simple potentiometer to be used in conjunction with millivoltmeter

Technique of Measuring Blood pH

The chamber (fig 1,B) is filled and sucked out several times with distilled water and finally with A R acetone to dry the chamber The stopcock is opened to allow the KCl just to reach the top of the capillary, then closed It is important not to allow KCl to enter the chamber, otherwise significant depression of the pH of the buffer will result owing to a salt effect, and reproducibility will be affected pH 6 835 buffer (a sample of which is kept in the reservoir water-bath) is introduced The glass electrode is lightly dried with filter-paper and inserted The millivoltmeter is switched on to the 100 mV scale After three minutes the potentiometer is adjusted until the millivoltmeter reads between 0 and 10 mV, and an accurate reading is taken On this scale the meter may be read to ±0 1 mV (±0 002 pH units) The buffer is then sucked out and the chamber washed with distilled water and dried with acetone The glass electrode is washed and stored in distilled water in the duplicate chamber The KCl liquid junction is now renewed The glass electrode is withdrawn and dried with filter paper Blood is introduced into the chamber from a syringe with a long needle, which reaches to the bottom of the chamber The glass electrode is immediately inserted and an accurate reading is taken at 1½ minutes The difference in mV multiplied by 0 0162 gives the pH difference between buffer and blood The figure 0 0162 is the theoretical factor relating pH to mV, it is derived from the expression F/0 0023026 R T, where R is the gas constant, F the faraday, and T the absolute temperature In our experience the electrodes may not give exactly this response, so, for more accurate work we allow for this error and any others inherent in the method by calibrating the glass electrode with the pH 4 025, pH 6 835, and pH 9 070 buffers We have found the response linear over this pH range, and in terms of the conversion factor from mV to pH units this response has remained constant within 0 00005 for any one electrode for at least three months

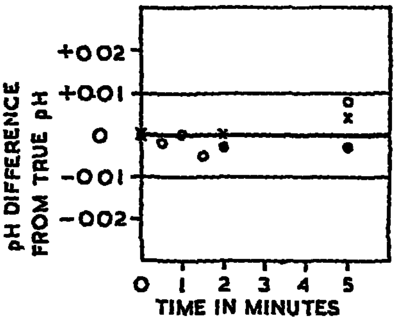

Fig 3—The pH of a sample of blood was measured in the usual way as described in the text. The measurements were repeated after various times of exposure in chamber before electrode was inserted Experiment was repeated thrice Horizontal lines are true pH ± 2S D

The factor has varied from one glass electrode to another within the range 0 0163 to 0 0165 A glass electrode should be checked periodically by this method

Other biological fluids—The pH of other biological fluids may be measured by an exactly similar method using the scale of the millivoltmeter appropriate to the pH range

Some Factors Affecting Measurement of Blood pH

Collection and Storage of Blood

Blood is collected without bubbles into a paraffined or silicone greased syringe containing 0 04 ml (0 2 mg) of heparin per 10 ml of blood The needle is inserted into a cork until pH is measured Since electrolyte estimations are generally to be made on the same sample, fluoride is not added Moreover it is unnecessary because, under these conditions there is no change in the blood pH at room-temperature for at least 30 minutes If the syringe is placed immediately into iced water, there is no change

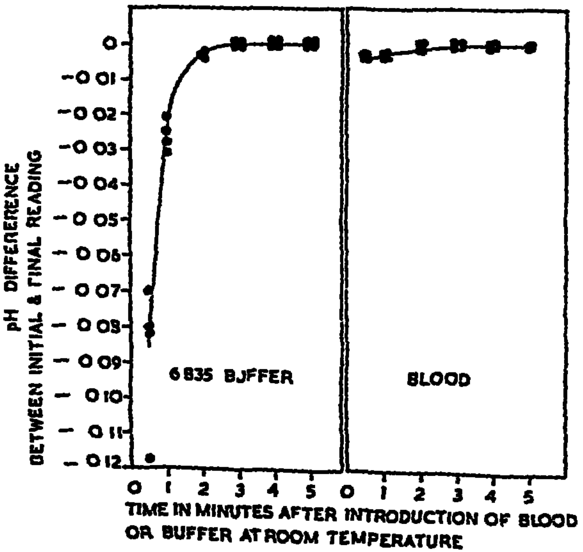

Fig 4—Effect of time after introduction of the sample and glass electrode into chamber, on pH of sample Experiment was performed four times and measurements were made at 38°C.

for four hours (Astrup 1956, Severinghaus et al. 1956, and personal observations).

Anaerobic Conditions

The best way to ensure anaerobic conditions is to send the blood to the laboratory in the syringe. Blood comes into contact with the atmosphere only in the brief period (a few seconds) between its introduction into the chamber and the insertion of the glass electrode. In any case, the blood finally in contact with the electrode has been protected from the air by the blood initially introduced, which is displaced upwards from the bottom of the chamber. By filling the chamber with blood and allowing it to remain exposed to the air for varying periods before the electrode is introduced, it can be shown that no significant pH change attributable to loss of carbon dioxide can be detected with up to 5 minutes' exposure (fig. 3).

Equilibration Time

When buffer is introduced at room-temperature, a steady reading is reached after 3 minutes, this being the time taken to reach thermal equilibrium. When blood is introduced, however, the time taken to reach a steady reading is less—about $1^1/_2$ minutes (fig. 4). This is because the negative temperature coefficient of the pH of blood almost cancels out the positive coefficient of the E.M.F.–pH relationship of this particular cell system.

Since the mV reading with blood remains constant for at least a further 3 minutes after equilibrium is reached, one may assume that the blood pH read after $1^1/_2$ minutes has not been measurably affected by glycolysis.

Reproducibility

The reproducibility of the measurement of the pH difference between two buffers with a pH difference similar to that between 6.835 buffer and blood was tested in the following way.

A buffer of mean measured pH 7.273 was made up, and the mV difference between this buffer and one sample of 6.835 buffer was measured nine times. The standard deviation of the mV differences, expressed in pH units, was 0.0025 (S_1).

A similar experiment was made with a sample of blood transferred anaerobically from a 20 ml. syringe to nine 2 ml. syringes, which were stored in iced water till the pH determination was made. The mean value for pH of the blood was 7.332. The mV difference between one sample of 6.835 buffer and each aliquot of blood was measured. The standard deviation of the mV difference expressed in pH units was 0.005.

The first experiment gives a measure of the reproducibility of measurement of pH with this apparatus. The second is a measure of the reproducibility of measurement of blood pH.

As a measure of the reproducibility with which pH 6.835 buffer may be made up, the mV difference between nine separate preparations of this buffer and one sample of 7.273 buffer was measured. The standard deviation of the mV difference, expressed as pH units, was 0.005 (S_2). By using the results of the first experiment to correct for errors in measurement, a standard deviation of pH .004 ($\sqrt{S_2-S_1}$) is obtained for the pH differences in the nine preparations of buffer.

Stability

We have found that over two to three hours successive introductions of 6.835 buffer give readings which agree to within 0.3 mV (0.005 pH) without adjustment to the potentiometer. These measurements were obtained during pH estimations on numerous samples of blood (about 12 per hour). This shows that repeated standardisations with buffer are unnecessary, at least over this time interval.

Discussion

It has become clear in the past few years that the estimation of the pH of the blood may be of great value in the diagnosis and treatment of numerous clinical conditions, especially those associated with disordered respiration. Respiratory failure is an emergency in which the blood pH and PCO_2 may need to be estimated quickly if correct treatment is to be given. In our efforts to develop a method of measuring the blood pH which would include simplicity, speed, accuracy, and above all reliability we have met with several difficulties.

Accurate control of the temperature of the glass electrode and measurement at the temperature of the patient is essential for blood-pH work. Temperature corrections may apply to normal blood but are unsuitable for pathological blood in which hæmoglobin, serum-protein, and electrolytes may differ greatly from normal.

The most vulnerable part of any system for measuring blood pH is the glass electrode. Until the past year we have used a slightly different electrode and have had a great deal of trouble from sudden unpredictable failure. Various gums were used to seal the pH sensitive bulb to the glass stem bearing the ground glass cone. We believe that the deterioration of the seal led to breakdown of the insulation and to erratic results. We have had no trouble from this source with the present electrodes, which are entirely glass sealed. The electrodes require no special cleaning and are stored in distilled water before use.

The liquid junction between the fluid being measured and the KCl salt bridge poses several problems for which many solutions have been suggested. We have found that a capillary works very well in practice. It has an advantage over porous fibres, sintered glass, and ceramic plugs in that, since protein is not precipitated in it, there is no special problem of cleaning.

The two types of instrument used for measuring the E.M.F. of a pH cell are the potentiometric (null point) and the direct reading. These both incorporate amplifiers for use with the high impedance glass electrode system, based either on electronic valves or dynamic capacitors. The pH cell described here works equally well with both types of instrument. The use of batteries or of accumulators as a source of power is a disadvantage in measuring blood pH, where it is often important to be able to take a reading at short notice. When the battery operated instrument is first switched on, 20 minutes are needed for warming up. If the instrument is left on, the power supply is rapidly exhausted. A mains operated instrument may be left running continuously and then needs no warming-up period.

Accuracy is of more importance here than in much pH work, so that the meter used must have a correspondingly better performance. For greatest accuracy a high zero stability is required if the zero setting is not to be checked constantly for drift. Here the dynamic capacitor has a considerable advantage over the valve operated amplifier because its stability is greater by a factor of at least 10. At the same time, a direct reading meter is simpler and quicker to use than a null point instrument. The chief requirements of a direct reading meter are linearity of response, meter accuracy, and stability of amplifier gain. These have been satisfactorily met in modern instruments.

The final problem to which we wish to draw attention concerns the standard buffer solutions used in blood pH work. The buffers we have described and the pH values ascribed to them have probably the widest acceptance in Great Britain and in the U.S.A. For the results of pH measurements of the accuracy required in biological work to be comparable from laboratory to laboratory it is essential to adopt a common pH scale, such as the Hitchcock Taylor scale described here. We have already mentioned that some intermediate buffers available commercially are far from their nominal value when tested. Others with whom we have discussed this point have had similar experience.

Summary

A method is described of measuring the pH of body-fluids anaerobically and at controlled temperature It is designed for small samples (0 5 ml) and is of suitable accuracy and reliability The method incorporates a specially designed pH cell which is used with a commercially made direct-reading millivoltmeter modified by the incorporation of a simple potentiometer to be suitable for pH measurements

Electronic Instruments Ltd , Richmond, Surrey, England, supplied the 'Vibron Electrometer model 33B, the glass electrode 18395, and the calomel electrode 18357 A pH cell and perspex box based upon our design and a suitable potentiometer may also be obtained from them Townson & Mercer Ltd , Croydon, England, supplied the thermostat bath and recirculating pump model 'BX 148/U' We wish to thank Dr G Mattock and Dr J Jackson for their helpful comments on the manuscript

Medical Societies

AMERICAN SURGICAL ASSOCIATION

THIS association's annual meeting was held in Chicago from May 8 to 10, under the chairmanship of Dr LOYAL DAVIS (Chicago, Ill.)

Injury Due to Atomic Explosion

Dr JOHN MORTON (Rochester, N Y) had seen Americans, Japanese, and Marshall Islanders burned by the fallout of radioactive dust following the explosion of the H bomb at Bikini Injury was mainly due to β irradiation causing epilation, vesication, and purpura superficially, with fever, vomiting, diarrhœa and failure of blood coagulation , mortality was approximately 50% in those exposed to 200r, 100% after 600r Ulceration starting at a late stage had been seen in some who had recovered from the acute effects

Dr J GARROTT ALLEN (Chicago, Ill) had studied the effects of γ-irradiation on dogs Though all had died after receiving 300r it was difficult to predict which would survive following lesser doses , 300–400r in a single exposure was fatal to man In dogs surviving non-lethal doses the white blood-cells returned to normal only after 30 days, thrombocytes after 50 days, and red blood cells after 75 days Supportive treatment with blood and platelet infusions and antibiotics during this period had no effect on the eventual outcome There was therefore no effective treatment, though shielding of the head at the time of exposure reduced mortality , additional shielding of the spleen and long bones improved the chances of survival Surgery for debridement of wounds and the reduction of fractures must be undertaken during the first 48 hours or after the 30th day since operative interference within this period caused death the real cause of which was not understood In the event of atomic war the policy of delayed primary or secondary suture would therefore have to be revised

Dr J BARRETT BROWN (St Louis Miss) referred to the dangers of exposure to electron streams for those working with cathode-ray tubes Accidents of this nature caused burns which became manifest 2–4 weeks later

Wound Infection

Dr CHESTER W HOWE (Boston, Mass) said that at the Massachusetts Memorial Hospitals the infection-rate after clean operations had been 1% in 1949 but had risen to 4% in 1953 and persisted at that rate till 1956 , the investigation concerned approximately 1200 operations each year Over the same period the incidence of infections with *Staphylococcus aureus* had increased from 57 to 80% and antibiotic-resistant strains had developed There appeared to be no relation to the staphylococcal carrier-rate, which was 99% in 1953 but had fallen to 73% in 1956 The increased incidence of infection had occurred wholly in patients operated on by the junior staff for in the private wards the incidence had remained at 1% throughout the period of study

Dr DERYL HART (Durham N C) said that ultraviolet radiation had solved this problem, and that operating-theatres so equipped were quickly sterilised

Dr HENRY T BAHNSON (Baltimore, Md) described 5 cases of staphylococcal bacteræmia and septicæmia following the use of silk sutures within the heart or great vessels , infection persisted until the sutures were removed and replaced by catgut or wire

Dr OSCAR CREECH, jun (New Orleans Louisiana), analysed 558 cases of tetanus seen between 1942 and 1956 , the mortality-rate had fallen from 43% in 1943 to 33% in 1956, and antibiotic therapy appeared to have been relatively ineffective Antitoxin was still the main line of defence , 75% of the deaths occurred during the first 4 days of the disease, and the outcome appeared to be related more to the amount of toxin produced than to the effects of treatment Only 1 case had been seen in a patient previously receiving *tetanus toxoid*

Complication of Œsophagogastric Resection

Benign gastric ulcer in 4 patients after œsophagogastric resection for carcinoma was discussed by Dr CURTIS A SMITH (Chicago, Ill), who suggested that it might result from delay in gastric emptying due to the inevitable vagotomy, since experimentally increased secretion in Heidenhain pouches had been found under these circumstances Gastro-enterostomy in 1 case had effected a cure for 6 years He felt that œsophagogastric resection should always be accompanied by gastro-enterostomy

Hypoparathyroidism

Peptic ulcer was one of the indications of hypoparathyroidism cited by Dr LEON GOLDMAN (San Francisco, California), the others being nephrolithiasis, bone lesions, and acute hypercalcæmia, in that order of frequency, though there were sometimes no leading symptoms The serum-calcium might not always be significantly elevated and he described a further diagnostic test involving the assessment of renal tubular reabsorption of phosphorus, which was low in 20 of 21 cases in which there was no uræmia

Calcium Metabolism

Dr GEORGE H CLOWES (Cleveland, Ohio) had seen hypotension unrelated to low blood volume during and after prolonged operations, particularly intrathoracic procedures incurring hyperkapnia and hypoxia causing respiratory and metabolic acidosis He found that the blood calcium fell before the end of the operation with an associated rise in circulating phosphate and lactate The protein bound fraction of calcium was not affected and the hypocalcæmia was due to a fall in ionised calcium , incomplete oxygenation might be a cause, as might citrate in blood replacement.

Nitrogen Balance

Dr WILLIAM D HOLDEN (Cleveland, Ohio) presented metabolic studies demonstrating that nitrogen deficit after surgical operations was due to a failure of adequate nitrogen intake in the postoperative period With appropriate intravenous nitrogenous intake using hydrolysates positive balance could be maintained, patients would not ingest sufficient nitrogen when left to eat what they wished, and the negative *nitrogen balance* under these circumstances exactly correlated with the degree of nitrogen starvation But, owing to tissue breakdown, equilibrium could not be obtained in *inflammatory states*

Cardiovascular Surgery

Dr CONRAD R LAM (Detroit, Michigan) showed the value of cardiac arrest induced by an intracardiac injection of acetylcholine while extracorporeal circulation was being maintained Intraventricular septal defects could then be sutured in a quiet dry heart, this had been achieved in 35 out of 50 patients operated on thus, the others having other cardiac defects There had been no increased incidence of atrioventricular block

Extracorporeal circulation had enabled Dr DENTON A COOLEY (Houston, Texas) to excise aortic aneurysms, the circulation being maintained from the left atrium to the left femoral artery for thoracic aneurysms, and from the thoracic aorta to the left femoral artery for upper abdominal aneurysms even when impinging upon the thorax

Dr C WALTON LILLEHEI (Minneapolis, Minnesota) had repaired a ruptured aneurysm of the sinus of Valsalva in 3 cases with the aid of extracorporeal circulation The patients were aged 10, 19, and 37, and the clinical histories revealed that the aneurysms had ruptured suddenly causing a fistulæ with a shunt of blood-flow from left to right heart, operative cures were complete

Dr W G BIGELOW (Toronto, Ontario) reported 20 cases in which open heart surgery was undertaken with only 2 deaths, using an improved method of hypothermia designed to avoid rewarming shock due to metabolic acidosis by avoidance of shivering and peripheral vasoconstriction with the use of chlorpromazine, and by inducing respiratory alkalosis during cooling and operation The use of heparinised rather than citrated blood had permitted ventricular fibrillation to be corrected when it developed

Dr CHAMP LYONS (Birmingham, Alabama) had used by-pass grafts to overcome the effects of thrombosis of the internal carotid artery Dr RICHARD WARREN (Boston, Mass) advocated arteriography in all hemiplegics since some cases were due to carotid thrombosis and were therefore treatable

Dr HOWARD MAHORNER (New Orleans, Louisiana) suggested that in massive thrombosis of femoral or subclavian veins the clot should be sucked out and a course of heparin be given, he had done 16 such operations with good results in 12

Dr WILLIAM G ANLYAN (Durham, N C) had studied 453 cases of venous thrombo embolism and in 19 had seen severe arterial spasm which was relieved by heparin, perhaps because of its antagonism to 5 hydroxytryptamine In half of 66 patients with pulmonary embolism there had been no clinical evidence of venous thrombosis elsewhere He could find no evidence of association between venous thrombosis and occult cancer, 792 cases of bronchial, gastric, and pancreatic carcinoma had yielded only 5 cases of thrombosis, in none of 26 cases of "idiopathic" thrombosis had full investigation revealed cancer

Cancer

Dr GEORGE E MOORE (Buffalo, N Y) had studied cancer cells circulating in the blood stream, in 52% of 179 cases of carcinoma at different sites and in 75% of cases of carcinoma of the stomach, malignant cells were seen in smears prepared from the peripheral blood Samples of blood were prepared by adding a fibrinogen heparin mixture and permitting gentle erythrocyte sedimentation, smears were made from the buffy upper layer, which contained white cells and malignant cells Scanning was tedious and required an average of 3 hours per case It was emphasised in discussion that many circulating malignant cells must be destroyed since there was no definite correlation on follow up between metastasisation and survival on the one hand and the earlier observation of circulating cells on the other Nevertheless Dr JULIAN JOHNSON (Philadelphia, Pa), who had followed 218 patients to 5 years after resection of the lung, had found only 3% survivors among those with vascular invasion as opposed to 71% among others, 88% survived 5 years when neither vessels nor lymph-nodes were involved Survival was related more to the absence of vascular than of lymphatic invasion

Dr MILLAR BELL (Chicago, Ill) presented experimental work showing that nitrogen mustard had a retarding effect on malignant cells injected into the portal vein of rats and was most effective when administered within an hour of the malignant inoculation

Dr WARREN H COLE (Chicago, Ill) was treating patients on these lines with appropriate control series, 65 patients with abdominal malignancy had been given nitrogen mustard 0 1 mg per kg body weight with a maximum total dose of 30 mg in three administrations, the first intraperitoneal and the others intravenous He said that this treatment should be avoided in patients over the age of 70, that leucopenia could be disregarded unless the white cell count fell by more than 3000, and that blood transfusions should be given from the 8th day to counter hæmopoietic depression

Dr R K GILCHRIST (Chicago, Ill) had been exploring the possibility of destroying the lymph gland field draining a malignant area by means of induced heat Fine particles of Fe_2O_3, 0 02–0 1 μ in size, would after injection pass to lymph glands but would not pass through them, high frequency currents of 12,000 watts applied externally rapidly raised the temperature in glands in laboratory animals

Dr JONATHAN E RHOADS (Philadelphia, Pa) made a plea for Whipple's type of operation in cases of pancreatico duodenal carcinoma, of 17 cases submitted to resection, there were 6 survivors for 5 years among those with growths of the ampulla of Vater, the common bile duct, and the duodenum, but none among those with cancer of the head of the pancreas Dr JAMES T PRIESTLEY (Rochester, Minn), however, had had 15% 5-year survival following excision of lesions of the pancreatic head

Choledocho-jejunostomy

Dr ALFRED M LARGE (Detroit, Michigan) had undertaken experimental work which indicated that biliary infection following choledocho jejunostomy occurred because of reflux through the stoma into the gall bladder, cholecystitis ensued with gall stone formation If the gall bladder was removed at the time of the anastomosis, infection did not occur in the biliary tree He presented clinical evidence to support his experimental findings and advocated cholecystectomy in association with biliary anastomosis to intestine Dr JOHN H MULHOLLAND (New York), on the other hand, did not regard reflux as the cause

Experimental Pancreatitis

Dr DANIEL W ELLIOTT (Columbus, Ohio) had shown experimentally that pancreatitis did not follow the reflux of bile into the pancreatic duct, but that pancreatic enzymes, which were secreted at a higher pressure than bile, passed into the biliary system where trypsinogen became activated on mixing with the bile, and the mixture, if then passed into the pancreatic duct, caused hæmorrhagic pancreatitis

Hepatic Cirrhosis

Dr **FREDERIC W TAYLOR** (Indianapolis, Indiana) had induced cirrhosis in animals by the repeated injection of silicon dioxide into the portal system over a period of 3 years; portal hypertension was not then associated with cirrhosis

It was observed by Dr **NATHAN A WOMACK** (Chapel Hill, N C) that venous dilatation in patients with cirrhosis was not always accompanied by a rise of pressure in the portal systems, the vascular dilatation might be hormonal

Dr **WILLIAM P LONGMIRE** (Los Angeles, California) had found that Evans-blue injected into the hepatic artery was immediately found in the portal system of cirrhotic patients, whereas in health there was a delay due to the usual circulation-time; this indicated an arterio portal shunt This view was supported by the work of Dr. **RICHARD M PETERS** (Chapel Hill, N C) in determinations of oxygen saturation in portal venous blood under experimental conditions

Dr **WOMACK** thought that the shunt might be in the gastric mucosa as demonstrated by Bentley and his colleagues at Newcastle upon Tyne.

Treatment of Ascites

Dr **CHARLES G NEUMANN** (New York, N Y) presented the results of ileo-entectrophy in 4 survivors of 10 patients treated thus for ascites A segment of ileum was resected, and with its mesentery intact its mucosal surface was exposed by opening the segment longitudinally close to the mesentery, cæcum and ascending colon were removed so that the ileal segment could be attached by its serosa to the right posterior abdominal wall, the omentum was removed, gastrostomy obviated postoperative intubation, which might have induced hæmorrhage from œsophageal varices Ascitic fluid had been absorbed in all 4 survivors The colon was not suitable for ascitic absorption, because of its greater tendency to secrete mucus

Hirschsprung's Disease

Dr **OVAR SWENSON** (Boston, Mass) presented the results of resection of aganglionic segments in 200 patients with Hirschsprung's disease There were 6 deaths and 5 lost to follow-up 73 patients had been followed for 5–10 years; 72 were well, 1 had recurrent diarrhœa To 5 years the figures were 64 followed, 63 well, 1 with chronic constipation, to 2 years 52 followed, 49 well, 3 with recurrent diarrhœa

Reviews of Books

Functions of Autonomic Transmitters

The Abraham Flexner Lectures, series no 13 J HAROLD BURN, M.D, professor of pharmacology, Oxford University London Bailliere, Tindall & Cox U S.A Waverly Press Inc 1956 Pp 228 40*s*

Professor Burn delivered the thirteenth series of Abraham Flexner lectures at Vanderbilt University last year They are now reproduced in this book

Two chapters are devoted to the actions of acetylcholine with special reference to its function in controlling contraction of heart muscle and ciliary movement A further chapter describes the actions of noradrenaline, and the problems associated with change in the sensitivity of denervated structures are fully discussed The common properties of local anæsthetics, drugs with a quinidine like action, spasmolytics and antihistamines are related to their ability to depress the action of acetylcholine in the tissues concerned Much of this fundamental research has been carried out in Professor Burn s laboratory, and he writes with the authority of many years spent in the study of the problems of autonomic transmission. The first and last chapters are of more general interest, dealing with some aspects of medical education and research the antidiuretic effects of smoking, and the influence of alcohol on motor-car driving

Physiologists and pharmacologists working in this special field will wish to have Dr Burn's book at hand In most of the chapters they will find interesting suggestions for further research

1957 Supplement to the British Pharmaceutical Codex 1954

London Pharmaceutical Press £1 7*s* 6*d*

THIS supplement contains 44 new monographs, including 10 which relate to drugs added to the *British Pharmacopœia* by the Addendum of 1955 The changing face of therapeutics is reflected in the inclusion of a substantial number of potent drugs such as acetazolamide, meclozine hydrochloride pentolinium tartrate, phenoxymethylpenicillin, and tetracycline hydrochloride There is a long list of older preparations which have been modified and the corresponding monographs have been appropriately amended

The importance of the *B P C* has been greatly increased in recent years by the inclusion of well-written sections on the actions and uses of the drugs listed Hence this publication is not only invaluable for pharmacists who need a book of reference which has a wider scope than the *B.P*, but is a first-class investment for the medical practitioner and specialist

Progress in Nuclear Energy Medical Sciences

Series VII vol I Edited by J C BUGHER, The Rockefeller Foundation, New York; J COURSAGET, C.E.A Society, J F LOUTIT Medical Research Council, A.E.R.E, Harwell. London and New York Pergamon Press 1956 Pp 165 42*s*

THE first volume of a series, this book is based on papers presented at the Geneva conference on the peaceful uses of atomic energy

Each of the seven chapters summarises in a slightly different way the work and papers of many authors, yet each remains a coherent account and not simply a list of statements and references The first four chapters deal with the main clinical medical uses of radioactive isotopes and the last three with radiation protection and legislation, and radiation dosimetry Industrial and general public-health aspects of radiation exposure and protection might perhaps have received fuller treatment Nevertheless, this is a good book and a useful work of reference

The Head and Neck in Roentgen Diagnosis

2nd ed Vols I and II EUGENE P PENDERGRASS, M.D, professor of radiology and chairman of the department of radiology, University of Pennsylvania, J PARSONS SCHAEFFER, M D, PH D emeritus professor of anatomy and director of the Daniel Baugh Institute of Anatomy, Jefferson Medical College, PHILIP J HODES, M D, professor of radiology, University of Pennsylvania Springfield Ill Charles C Thomas Oxford Blackwell Scientific Publications 1956 Pp 1759 £14

AFTER a lapse of fifteen years, another edition of this book has been produced, dedicated to the memory of Prof H K Pancoast, the original author The text has been completely rewritten and now covers every aspect of the radiology of the head and neck There are excellent chapters on the examination of the brain by angiography and ventriculography Throughout the book, the common and often misleading variations of normal are distinguished from the frankly pathological Diseases which may affect the head and neck, though they originate in other parts of the body, have been included The clinical and pathological as well as the radiological findings are incorporated in a straightforward narrative, backed up with enough detail of anatomy, differential diagnosis, and radiographic technique to make it one of the better textbooks available in the English language

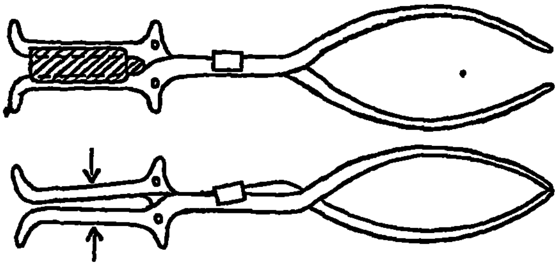
Lumbar Puncture and Spinal Analgesia (2nd ed Edinburgh and London E & S Livingstone 1957 Pp 142 25s) —The second edition of this very helpful little monograph by Sir Robert Macintosh will be as acceptable as the first in providing a refreshing approach to an old subject, by one who speaks from long experience and with mature opinion In the interval between the two editions the courts have decided some important cases in which neurological complications of spinal analgesia figured conspicuously This book emphasises clearly the importance of proper sterilisation in avoiding these complications

Regulation and Mode of Action of Thyroid Hormones (*Ciba Foundation Colloquia on Endocrinology* Vol 10 London J & A Churchill 1957 Pp 304 48s) —This is the report of a conference held last June under the chairmanship of Dr Rosalind Pitt Rivers and attended by speakers from Europe and North and South America The papers are edited by Dr G E W Wolstenholme and Miss Elaine C P Millar, A R I C

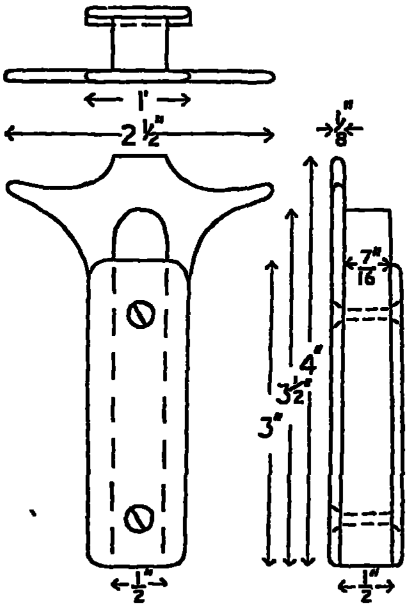
New Inventions

KIELLAND'S FORCEPS HANDLE-LOCK

THE sliding-lock mechanism of Kielland's obstetric forceps, which is necessary for the easy articulation of the blades and for the correction of asynclitism, results in a gap between the handles and a lack of stability Any grip applied to the handles with the forceps correctly applied will cause a crushing force to the fœtal head



The handle-lock illustrated is made of stainless steel and is applied after asynclitism has been corrected It ensures a firm grip of the handle without any tendency to crush the head It produces perfect alignment of the blades, and, because the Kielland's handles are wedge shaped it will not slip off



Holborn Surgical and Veterinary Instruments Ltd , Margate Road, Broadstairs, are proposing to make the handle lock in solid stainless steel

A MODIFICATION OF THE TONGUE-PLATE OF THE BOYLE-DAVIS GAG

IN oropharyngeal surgery, tracheal intubation is well recognised as a valuable means of maintaining control of the airway at a light level of anæsthesia The disadvantages of intubation by the nasal route are such that there may be a place for a means whereby it can be avoided in the commonest of all oropharyngeal operations—namely, tonsillectomy

A simple modification of the tongue-plate of the Boyle Davis gag allows tonsillectomy in children and adults to be performed after orotracheal intubation without the tube encroaching on the field of operation (fig 1)

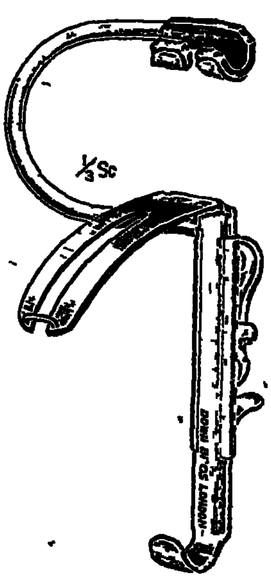

Fig 1

A slot is cut in three quarters of the length of the tongue plate and the lingual aspect of the slot bevelled to accommodate the tube A metal bridge is fitted at the distal end of the slot to prevent the tube wedging in it The lingual surface of the tongue plate proximal to the slot is grooved slightly to hold the tube centrally

Anæsthesia is induced and an endotracheal tube is passed through the mouth This is fixed so that it lies centrally over the tongue, lips, and incisor teeth The surgeon then inserts the gag by sliding the bridge at the distal end of the tongue plate over the tube within the mouth Care must be taken at this stage to ensure that the central fixation of the tube is not disturbed

The tongue plates are made in three sizes, the largest being suitable for adults (fig 2) It is recommended that Magill's tubes sizes 1–3 be used with the 3 in tongue plate, sizes 3–6 with the 3½ in tongue plate, and sizes 7–10 with the 4 in tongue plate

Tongue-plates incorporating a similar idea have been described previously[1,2] This modification, which was introduced at the section of anæsthetics of the Royal Society of Medicine on March 1, is recommended on the grounds of simplicity and the fact that standard tongue plates may, if desired, be modified by the manufacturers

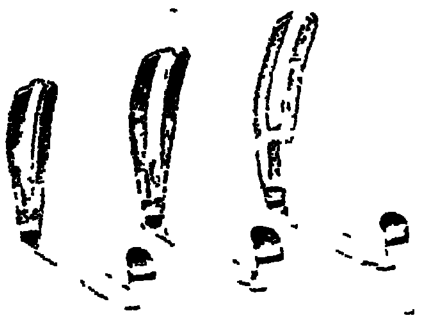

Fig 2

The modified tongue plates may be obtained from Messrs Down Bros and Mayer & Phelps Ltd , 32, New Cavendish Street, London, W 1

THE LANCET

LONDON   SATURDAY, MAY 25, 1957

The Immunology of Thyroid Disease

A year ago it might have seemed preposterous to suggest that immunology had anything important to contribute to the study of diseases of the thyroid gland. Yet on May 8 the section of experimental medicine of the Royal Society of Medicine was able to hold on this topic a full-length discussion whose liveliness showed clearly that a new and stimulating idea has been injected into medical thought.

The guest of honour was Prof. E. Witebsky, whose main interest for the past twenty-eight years has been organ-specificity as demonstrated by immunological reactions particularly in relation to the thyroid gland. In the past few years he and his colleagues at Buffalo have been observing the response of animals to the injection of extracts of thyroid glands derived from the same species. These observations have driven Professor Witebsky, with considerable reluctance, to admit that true auto-antibodies can be formed—a conclusion which appears to defy the principle of *horror autotoxicus* enunciated many years ago by his old master Ehrlich. Witebsky and his colleagues have actually demonstrated that a rabbit can make antibodies against an extract of its own excised thyroid. These antibodies are by no means merely an academic curiosity, for they have been shown to be associated with constant and often severe damage to the animal's thyroid when this has been left in situ.[1]

Professor Witebsky relates that it was his colleague at Buffalo, Dr. Douglas Riggs, who first looked down the microscope at sections of the damaged thyroids of his rabbits and made the significant remark: "That looks like Hashimoto's thyroiditis." Witebsky was quick to follow up the implications of this comment, and soon showed that in clinical cases of Hashimoto's thyroiditis (lymphadenoid goitre) there were circulating antibodies against extracts of human thyroid gland. He was slow to publish his results, and he has been anticipated by the entirely independent observations made at the Middlesex Hospital by Dr. Roitt, Dr. Doniach and their colleagues.[2] These workers started from the observation (already recorded by Fromm et al.[3] and by Luxton and Cooke[4]) that patients with Hashimoto's thyroiditis tend to have an unusually large amount of circulating γ globulin, commonly associated with abnormal flocculation tests. Doniach and Roitt had the happy thought that the excess γ globulin might actually represent circulating antibody. They made an extract of normal thyroid gland, added it to serum from patients with Hashimoto's thyroiditis, and obtained easily demonstrable precipitates. The amount of these precipitates is quite startling to immunologists, who normally regard the human animal as a poor producer of precipitating antibodies.

The next development was that both Witebsky, and Roitt and Doniach, showed quite clearly that purified human thyroglobulin could replace thyroid extract for the demonstration of these reactions. Similarly the rabbit antibodies and thyroid reactions can be evoked equally well by the use of rabbit thyroglobulin. Professor Witebsky added the warning that no-one so far has obtained a thyroglobulin which can be regarded as pure; the preparation made in his own laboratory, which he thinks is probably the best yet made, still contains 5% or more of impurities. Provisionally, however, it seems to be agreed that thyroglobulin itself is probably the antigen which provokes the auto immune response, and this idea is supported by studies with fluorescent antibodies. By this technique Professor Witebsky found that when labelled antibody is brought into contact with sections of rabbit thyroid it becomes concentrated mainly in the region of the colloid within the acini. Dr. R. G. White, of the London Hospital, has done the same thing with human thyroids, using serum from cases of Hashimoto's thyroiditis, and here too the antibody was concentrated in the colloid. To remove any doubts about the possibility of irrelevant iso-antibodies he has demonstrated the same phenomenon in the thyroid of a patient with Hashimoto's thyroiditis, applying the patient's own serum. Again the antibodies collected in the colloid of the few remaining active acini, providing convincing evidence of auto-immunity caught in the act. Small amounts of antigen (detected by the labelled antibody) also appeared to be present in some of the cells which invade the thyroid in large numbers in this disease.

Dr. White had also made use of the fluorescing technique to detect the corresponding antibody. The adjacent lymph-nodes are often enlarged in Hashimoto's thyroiditis, and White very reasonably argued that this might be because they were called on to produce at least a large part of the antibody to thyroglobulin. He took one of these lymph-nodes and applied to it first thyroglobulin, and then labelled antibody to detect the thyroglobulin. The marker collected in discrete spots which could be interpreted as the sites of antibody formation. On the basis of these results he put forward the suggestion that antibody is formed in three stages. An initial leak of thyroglobulin attracts a collection of lymphocytes and plasma cells within the thyroid, which themselves make antibody locally. Cellular destruction resulting from the antigen antibody reaction may cause the release of more thyroglobulin, thus initiating a sort of chain-reaction. Some of this thyroglobulin escapes into the surrounding lymph-nodes, where the second stage of antibody formation is stimulated. Finally some thyroglobulin gets into the general circulation, so that antibodies are produced by other tissues and become demonstrable in the serum.

There is still some uncertainty as to the best way of demonstrating the circulating antibodies. The first method to be employed was that of simple precipitation. In suitable cases this method can be most spectacular, but it is not very sensitive. By this method in Britain precipitating antibodies have been found in only about half the cases of Hashimoto's thyroiditis, and Professor Witebsky's experience in Buffalo has been even more disappointing. He prefers a method in which tanned red cells are coated with antigen and then agglutinated by the antibody. In his hands this technique has been specific and astonishingly sensitive, both in rabbits and man, with serum titres up to the fantastic figure of 1 : 2,000,000. Yet even with this sensitive instrument he could still detect antibodies in only a minority of cases of Hashimoto's thyroiditis. The discrepancy between his results and those of the British workers may lie in the realm of diagnosis; at least this seems a more likely explanation than that some radical difference exists between Hashimoto's thyroiditis in Buffalo and in London Pathologists are by no means agreed as to which cases should be called Hashimoto's thyroiditis, and which are better described as chronic non-specific thyroiditis Possibly before long the responsibility for diagnosis will be taken over from them by the immunologists The third—and most controversial—method of detecting antibodies is by complement-fixation Professor WITEBSKY has had no success with this method in man, though it is sensitive and reliable in detecting antibodies in immunised rabbits Dr ROITT likewise has had little success in detecting antibodies in this way Dr WHITE, on the other hand, using thyroglobulin prepared from thyrotoxic thyroids as his antigen, has been able to detect complement-fixing antibodies in nearly all cases of Hashimoto's thyroiditis which he has examined So, too, has Dr J R ANDERSON, of Glasgow, his antigen is an extract of thyrotoxic thyroid Dr W R TROTTER, Dr G BELYAVIN, and Miss A WADDAMS, of University College Hospital, have had a mixed experience At first, using an extract of normal thyroid as their antigen, they were quite unable to detect complement-fixing antibody, but later, using an extract of thyrotoxic thyroid, they found antibodies in almost all their cases of Hashimoto's thyroiditis Their preliminary separation experiments with an extract of a thyrotoxic gland indeed suggest that the precipitating and complement-fixing antigens may be distinct substances This suggestion is interesting in that it implies that the complement-fixing antigen may be specific to thyrotoxicosis, which would at once broaden the scope of the investigation to include this mysterious disease But both Dr WHITE and Dr ANDERSON have obtained complement-fixation with extracts of normal thyroid, though the titres were much lower than with thyrotoxic thyroids At least all workers seem to agree that for complement-fixing tests thyroid extracts from patients with thyrotoxicosis provide the best antigen Complement-fixing antibodies have been found in nearly all cases of Hashimoto's thyroiditis, in at least half of all cases of spontaneous myxœdema, in a substantial proportion of cases of thyrotoxicosis, and occasionally in normal subjects This distribution is reminiscent of the distribution of what is often termed lymphadenoid change—that is, destruction of thyroid tissue and its replacement by an infiltration of lymphocytic cells There may well be a correlation here, but it has not yet been proved

It now seems that the initial event in Hashimoto's thyroiditis is the leakage of thyroglobulin out of the thyroid acini Within the acinus thyroglobulin may be supposed to lead a secluded life, cut off from all contact with antibody-forming cells Hence it dodges the principle of immunological tolerance so ably expounded by Prof P B MEDAWAR, F R S, and his colleagues The body's antibody-forming cells are not introduced to thyroglobulin in fœtal life, so it remains a stranger to them for ever after To these cells a stranger is a foe A small leakage of thyroglobulin therefore immediately attracts the attention of wandering antibody-producers, they collect in the thyroid, cellular destruction follows and more thyroglobulin is liberated, whereupon more antibody is produced It is easy to see that such a process, once set going, may be self-perpetuating This picture is an attractive one, and remarkably complete In fact leaves only one thing unexplained what sets t process going ? No-one so far seems able to provid satisfying answer to this question We should, ho ever, be well content with the progress made in a ve short time The invasion of the thyroid field by t immunologists has begun well The troops have be got ashore, and have secured a beachhead T subsequent development of the operation should well worth watching

Towards Safer Clothing

THE past hundred years have seen great chang in the clothing materials used by women and childre Woollen garments, including flannel, and natur silk have been largely replaced by cotton fabri and artificial silks (rayons), and, in general, the newer fabrics have been of lighter weight—in oth words, less closely woven These changes hav considerably increased the risk of serious burning accidents The woollens and natural silks did not ignite easily, and, if they did catch fire, the flame did not spread rapidly so much is known to every man who has scorched his trousers standing by a fire But with the cottons and rayons—especially those of light weight—the sequence of events is very different Momentary contact (2–4 seconds) with a flame or the element of an electric fire is enough to ignite the material, and within half a minute most of a child's nightdress may be burning fiercely—especially if, as often happens, she runs about in terror and so fans the flames By the early days of this century it was apparent that the increasingly popular *flannelette*—i e, cotton material with a slightly fluffed-up surface—was associated with many fatal accidents to children In 1905 *The Lancet* declared "The days of flannelette should be speedily numbered" In 1908 the Home Office appointed a committee to consider the matter, but before any effective action could be taken the 1914–18 war diverted attention In the past fifty years there have been something like 25,000 deaths from clothing burns in England and Wales, and about four times that number of people have received very serious injuries After the 1939–45 war COLEBROOK and his colleagues [1–5] repeatedly called attention to the matter, stressing the danger of unguarded heating appliances and also of highly flammable clothing materials In 1952 Parliament passed the Heating Appliances (Fireguards) Act, and in 1956 specifications for a standard guard for coal fires were issued by the British Standards Institution [6] These measures will certainly help to reduce the risk of clothing accidents in homes But the menace of highly flammable clothing remains

To deal with this a committee was set up in 1956 by the British Standards Institution, and its report has now been published [7] The committee was fortunate in that a preliminary investigation had just been made by D L LAWSON and his colleagues

[7] *The Flammability of Apparel Fabrics in Relation to Domestic Burning Accidents* B S I 1957 PD 2777

in the laboratories of the Fire Research Organisation and the Department of Scientific and Industrial Research into the different methods of assessing the flammability risks associated with various clothing fabrics[8] By an ingenious device which measures accurately the time taken for flame to travel vertically upwards over 100 inches of the material under test, LAWSON et al had established the "flame-resistance rating" for a large number of fabrics Broadly speaking there were three categories the very light-weight materials, such as organdie, over which flame travelled 100 in in 8–25 seconds (that is their ratings were expressed as 8–25), the medium-weight cottons and viscose rayons, including flannelette and winceyette and mixtures of these with wool which had a rating of 25–70, and the medium and heavy weight woollens, natural silks nylons and 'Terylene' (if untreated with flammable "finishes"), and some flame-proofed fabrics, all of which had a rating of 100–300 A subsequent study of 82 garments which had been involved in clothing burns showed that the great majority were of materials in the middle group, rated at 25–70, the most common having a rating of 40–50 Few burns had been caused by the most highly flammable materials (rated at 8–35), not because these are not dangerous, but because they are seldom worn by comparison with the materials rated at 25–70, many of which are in daily use—for instance, for children's nightdresses and women's dresses None of the 82 burns had been caused by materials rated above 140

In the light of these findings the committee considered whether all clothing fabrics offered for sale should in future be graded according to their flammability rating, but it finally decided that this would not at present be in the public interest Instead it concluded that a "level of safety" should be designated and that fabrics rated at or above that level "should be warranted as such and identified accordingly"—presumably by the familiar B S I kite mark Fabrics so marked will not, of course, be guaranteed as completely non-combustible (all fabrics will burn if exposed long enough to sufficient heat) but garments made from them will burn so slowly if they should catch fire, that the wearer will have a good chance of putting out the flame before it has spread enough to cause a serious burn This designation of a level of safety should prove a notable advance But there is one difficulty Under the Fabrics (Misdescription) Act, passed in 1952 and now largely forgotten, it became an offence to describe a material as possessing "in any degree" the quality of 'non inflammability' unless it passes a very stringent test (failure to ignite on exposure to flame for 12 seconds) A few fabrics which reach the level of safety now proposed by the committee might just fail to pass the severe test of the 1952 Act, and so could not legally carry the B S I safety mark To get over this difficulty the Act may have to be repealed

The committee also stresses the importance of pressing on with the development of "flame proofing" processes, which would bring many cottons and rayons within the safety zone It calls attention once again to the importance of avoiding loose-flowing garments—e g, nightdresses for children—and to the overriding need for guarding all heating appliances Finally it emphasises that more effective propaganda is required to make the public aware of the risks of clothing burns and more eager to demand safe materials Doctors can help to eliminate clothing burns by advocating safer clothing materials and passing on the committee's other recommendations—especially with regard to the guarding of electric and gas fires bought before the Fireguards Act came into force

Cutaneous Pain

APPARENTLY various cutaneous sensations can be painful, but it is not now believed that intense stimulation of nerve-endings of any type can cause pain On the contrary, it is thought that the specialised nerve-ends can respond only to appropriate stimuli and that all forms of pain arise from the unencapsulated free nerve-ends which lie among the epidermal cells The nerve-fibrils from these run into a nerve-net, or delta, which in turn unifies through branches, to become a pain-carrying nerve-fibre There is overlapping, but not continuity, of peripheral-nerve nets Anatomically somatic sensory-nerve fibres are divided into C fibres, which are small in diameter and along which impulses travel more slowly than in the other, or A fibres Thus the shape and timing of the electrical potential changes during the passage of an impulse are typical and recognisable It is possible, then, to apply to skin various stimuli known to be painful and at the same time record the potential changes in the sensory nerve, the pattern of these being a clear pointer to the type of nerve-fibre carrying the impulse From evidence such as this it has been shown that the thinnest and most slowly conducting fibres of the A group are responsible for carrying the sensation of immediate or first pain, and that C fibres, conducting even more slowly, give rise to delayed or second pain With this limited number of fibre-types, how is it that pain can vary not only in degree but in quality and can be elicited by a wide variety of stimuli—all of which, incidentally, are calculated to damage tissues[2] That the nerve-ends are undifferentiated probably accounts for the range of physical and mechanical stimuli to which they respond Many of the apparent differences in sensation depend on the duration as well as the intensity of the painful stimulus, for pain differs from most other types of sensation in that it does not adapt, or decline with time Some of the differences depend on central ramifications The pain nerve-ends also react to chemical stimuli and some workers find it difficult to account for all the features of pain especially abnormal types, without postulating the release of a chemical from damaged tissues This substance might act by sensitising the nerves—i e, reducing their threshold—or by causing them to discharge even after the painful stimulus has long ceased In this connection LEWIS[1] tested skin extracts and found that they had pain-producing properties, and he went far towards defining the conditions in which they were most effective He did not identify the substance responsible, but believed that it was not histamine

One of the difficulties of this subject is to develop a means of measuring and recording the intensity and duration of pain. One method is that used by **Keele** and his co-workers,[2] which depends on the subject's estimate of pain but gives reproducible results. According to the intensity of pain the subject gives more or less of a turn to a handle which raises or lowers a pointer writing on smoked paper. In this way a permanent record is obtained of the intensity, duration, and fluctuations in the pain felt. **Keele** et al.[3] placed solutions of substances to be tested on the exposed base of a blister made by a standard method—usually by application of a small cantharides plaster. The subject was, of course, unaware of the nature of the solutions applied. It was found that high dilutions of acetylcholine (ACh) were immediately painful; 5-hydroxytryptamine (5-H.T.) gave rise to delayed pain; and histamine diluted 10^{-3} or 10^{-4} times was painful, but when diluted 10^{-5} or 10^{-6} times caused only itching. The action of these three compounds, which are widely distributed in body tissues and fluids, was compared with that of some of the body-fluids themselves. Blister fluid, for instance, immediately after collection had no pain-producing substance (P.P.S.); if the fluid was kept in a silicone-lined container P.P.S. developed only slowly, but if the fluid was in contact with glass P.P.S. appeared in a few minutes. The same behaviour was seen in other exudates, such as that from the knee-joint of patients with rheumatoid arthritis, from pleural effusions, and from protein-rich ascitic and hydrocele fluid. Human whole blood also reacted similarly. Pain-producing activity was greatest after five to eight minutes and then began to decline until after about an hour 90% of activity had gone. Were these fluids pain-producing because of their content of the fairly simple substances previously tested? With the help of another test the answer was found to be No. Originally the search was for a method more convenient than the frequent blistering of friends and other volunteers, as well as for some means of accurately comparing known chemicals with the unknown P.P.S. in mixed fluids. The isolated rat uterus suspended in a bath of saline solution proved useful. First, it was found that P.P.S. caused the uterine muscle to contract, and that, whereas the action of ACh was antagonised by atropine, that of P.P.S. was not. Histamine though causing pain had not caused the uterus to contract, and diluted P.P.S. did not cause itching. H.T. was at first the most probable candidate for the position of P.P.S., but, again, substances which blocked the action of H.T. on the uterus did not block that of P.P.S.

[8] Lawson, D. L., Webster, C. T., Gregsten, M. J. J. Text. Inst. 1955, 46, T [illegible]

[1] Lewis, T. The Blood Vessels of the Human Skin and their Responses London, 1927

The activation of body-fluids by contact with glass suggested some similarity to blood-clotting, and it was further found that protein-poor fluids did not produce P.P.S., but there were dissimilarities that ruled out any direct relationship. Possibly P.P.S. is linked with some early stage of thromboplastin formation; but the evidence suggested that it might be a breakdown product of protein, possibly a polypeptide. By comparative tests the chemical and physiological behaviour of P.P.S. and bradykinin were found to be closely alike. Now, proteolytic enzymes abound in tissues, and it is known that in normal conditions stimulation of the chorda tympani nerve releases from the submandibular gland an enzyme which acts on plasma to form a bradykinin-like substance.[4] Also, tissue damage releases an active proteolytic enzyme from skin.[5] There is, then, nothing unreasonable in the idea that injured tissue may release an enzyme which acts on some component of plasma-proteins to form bradykinin, or something very like it, and that this substance causes pain, as it can be shown to do. During the time it is present in the tissues it may well affect the nerve threshold to other forms of stimulus. The decline in P.P.S. activity of body-fluids is probably due to the presence of other enzymes which hydrolyse it to an inactive state. If indeed bradykinin and P.P.S. prove to be identical, or even if bradykinin is only one of a group of similar substances, that is an important and useful step towards further understanding of the great problem of pain.

TELEVISION AND MEDICINE

Television was first publicly demonstrated in Great Britain in 1928, and in the same year John Baird demonstrated colour television. A surgical operation was first televised in black and white (at the Johns Hopkins University) in 1947, and in colour (at the American Medical Association's convention in Atlantic City) two years later. Since then television for medical meetings and teaching has been developed extensively in the United States, and closed-circuit units have been installed in hospitals in London, Paris, and elsewhere. The first colour-television demonstrations of surgery in Great Britain will take place this summer.

Television is particularly suitable for demonstrating new or modified operative techniques to surgical colleagues. Because of its immediacy it is valuable for illustrating a talk, and the surgeon can discuss with his audience the rationale of each stage as he performs it. But there is a risk that the selected patient may prove unsuitable for the intended operation or that routine steps, such as procuring hæmostasis, may take unduly long. Both of these disadvantages may be avoided by using film; and rare or unique operations, such as the separation of conjoined twins, demand a permanent record, so here film has an undisputed advantage.

In medical schools television has little to commend it. A reel of film is shown much more easily—*and cheaply*—than a television demonstration requiring on each occasion, in addition to the clinical material, cameras, lighting equipment, crew, production staff, and lecturer. But conceivably a programme originating in one school might be broadcast to several others so that students might benefit from teaching sessions at several centres in addition to their own. Such a scheme has been attempted in the United States, where a handbook has been prepared for producers of medical television programmes.[6] It is becoming increasingly recognised that a medical student gains little from watching operations on a screen; in the short time he spends in the operating theatre as an undergraduate he should learn primarily the conventions of sterile techniques and how to assist a surgeon usefully. This is now appreciated by most British film makers, and only some 6% of the 1700 medical films available here show surgical procedures. Television might be applied more usefully to demonstrating cytological and bacteriological slides; and it may also prove useful as an image intensifier in conjunction with radiographic screening.

For the non specialist, television has an important future in public-health education and programmes of general medical interest. In America medical cases are presented in at least one regular weekly programme and in France endoscopies have been demonstrated on the national television service.

WHEEZING

WHEEZING is the most obvious sign of an acute asthmatic attack. Like many other familiar phenomena, it has had comparatively little serious thought, and until quite recently hardly anyone has suggested that it may not arise (as generally supposed) from the passage of air through constricted bronchioles. The paper we publish this week by Dr Dekker and Dr Groen should serve at least as a basis for a review of the prevalent ideas. Briefly, they maintain that the wheezing sound is generated in the larger bronchi and trachea by the rapid and turbulent flow of respiratory gases through them when they are constricted by pressure from without: the pressure is applied within the thorax by the force of expiratory muscular contraction against the high resistance to gas flow offered by the constricted bronchioles. In their scheme of events bronchiolar constriction does not itself cause wheezing at all.

This explanation is not so unlikely as it may seem at first. One point in its favour is that the actual volume of gas flowing through a bronchiole during expiration must be very small indeed and probably flow is streamline in character; these are not the conditions in which one would expect audible sounds, which require that flow should be turbulent and be of enough volume to generate sound waves of suitable power and frequency. A clinical observation which adds support is the well-known "pursed lip" breathing often seen in emphysematous patients. By adopting this mode of expiration, pressure is built up within the bronchial tree which helps to prevent collapse of the larger branches.

The investigations on normal people are of interest in relation to so called psychogenic asthma. It is easy to see how patients with anxiety states might acquire the same trick of wheezing expiration—and also why their asthma might be completely cured by psychotherapy.

VITAMIN D AND THE PARATHYROIDS

WHEN Albright and Reifenstein[1] drew attention to the similarities between the metabolic effects of vitamin D and of parathyroid hormone, they were not convinced that either exerted a direct "calcæmic" action on bone; but since then both substances have been found to possess this property. Thus experimentally it has been shown beyond doubt that parathyroid extract raises the serum-calcium even after nephrectomy[2] and that vitamin D raises the serum calcium of rachitic rats in conditions which make it impossible to ascribe this effect to increased absorption of calcium from the intestine.[3] The close similarity between the effects of vitamin D and of parathyroid hormone on bone is underlined by Barnicot's observation[4 5] that local implants of calciferol and parathyroid-gland tissue evoke the same osteoclastic reaction.

The inference that vitamin D and parathyroid hormone are both concerned in regulating the equilibrium which is believed to exist between the calcium and phosphate ions in the extracellular fluid and the crystals of a calcium-phosphate compound in the skeleton[6 7] may shed some light on related problems. It explains the hypercalcæmia which may be induced by very large doses of vitamin D (never adequately explained by the action of vitamin D on absorption of calcium), and it may account for the secondary hyperparathyroidism often seen in rickets and osteomalacia. If vitamin D normally contributes to the maintenance of the serum-calcium level, its deficiency would tend to lower the calcium content and stimulate the parathyroid glands, leading to the parathyroid hyperplasia seen in rickets,[8] and to the radiographic[9] and histological[10] manifestations of parathyroid overactivity reported in osteomalacia. In fact, such parathyroid overactivity is very probably responsible for the high phosphate-clearance observed in osteomalacia,[11] and so for the low serum-phosphate in this condition which cannot be attributed to malabsorption of phosphorus. But lack of vitamin D does not always set in train this course of events. Hypocalcæmic tetany is another familiar manifestation of this deficiency; but its precise relationship to rickets has never been fully understood. If rickets is regarded as a manifestation of secondary hyperparathyroidism, hypocalcæmia may legitimately be regarded as an indication of parathyroid insufficiency, particularly when—as is often the case—the content of inorganic phosphate in the serum is high. The reason for this parathyroid insufficiency is unknown.

Nutritional deficiency of vitamin D has become a rare cause of rickets and tetany, but both these conditions may arise in steatorrhœa. They are then indistinguishable from the corresponding conditions produced by nutritional deficiency (except in the dosage of oral calciferol which they need), and are commonly attributed to malabsorption of fat-soluble vitamin D,[12] though Dent[13] has suggested that there may be some additional metabolic disorder present. In a letter on p. 1086, Dr Jackson suggests that steatorrhœa and hypoparathyroidism are significantly associated, and he draws attention to reported cases presenting both disorders. He cites the attractive suggestions of Salvesen and Boe[14] that patients with steatorrhœa may develop either osteomalacia or tetany according to the response of their parathyroids to hypocalcæmia; and he suggests that some particular significance should be attached to the apparently high prevalence of parathyroid insufficiency in steatorrhœa.[15] There may, of course, be evidence of endocrine insufficiency in steatorrhœa,[16] and possibly parathyroid insufficiency should be regarded as a particular manifestation of this general disorder; in fact, amenorrhœa and 'absent' body hair were prominent features in Dr Jackson's own case.[17] If, on the other hand, these patients are in fact suffering from a deficiency of vitamin D, it seems more reasonable to seek a single explanation for the tetany of steatorrhœa and that of nutritional avitaminosis D.

The hypothesis that the parathyroids either respond to hypocalcæmia and cause osteomalacia, or fail to respond and cause tetany, seems to be an oversimplification. Thus it fails to take into account or to explain the vital fact that tetany and rickets may be found in the same patient. This is true not only of nutritional vitamin-D deficiency, in which tetany is almost invariably associated with rickets, though rickets is only occasionally accompanied by tetany,[18] but also of the malabsorption syndrome.[19] In both types of vitamin-D deficiency, however, it seems that whereas rickets may precede tetany, tetany rarely if ever develops into rickets.[18]

These observations can be reconciled if it is accepted that the parathyroid glands may become "exhausted." On this hypothesis, an indeterminate period of parathyroid overactivity may lead to rickets or osteomalacia, but may culminate in parathyroid failure and tetany. The two possible parathyroid responses postulated by Salvesen and Boe can be regarded as the two extreme examples, but between them there can exist every degree of parathyroid activity represented by different combinations of serum contents of calcium and phosphate. A normal serum-calcium with a low serum-phosphate suggests complete parathyroid compensation; a low serum calcium with a high serum-phosphate, complete parathyroid failure. Between these two extremes, the development of rickets will depend on the product of Ca × P in the extracellular fluid, and the development of tetany on the absolute content of calcium ions.

The possibility remains that the hypoparathyroid state is more common in steatorrhœa than in nutritional vitamin-D deficiency, or that it differs in some other way in the two conditions. If Dr Jackson can show this to be the case, his suggestion will be greatly strengthened.

THE ENZYME DEFECT IN GALACTOSÆMIA

Two years ago[1] we discussed the genetically determined inborn error of metabolism known as galactosæmia. Some of the questions raised then remain unanswered —for example, whether children with this metabolic error would be entirely protected from harm if they were kept on a lactose-free diet from birth. But another problem —the exact nature of the enzyme deficiency—has been solved. In 1955 Schwarz et al.[2] had taken the first step by showing that the red cells of galactosæmic children who had just had a milk feed contained an accumulation of galactose-1-phosphate, but not of glucose-1-phosphate. Therefore galactose was being metabolised to galactose-1-phosphate, but a stage in the conversion of galactose-1-phosphate to glucose-1-phosphate was imperfect.

This transformation involves three stages. First, galactose-1-phosphate combines with uridine diphosphoglucose to give glucose-1-phosphate and uridine diphosphogalactose. Second, uridine diphosphogalactose is transformed to uridine diphosphoglucose. Third, uridine diphosphoglucose reacts with inorganic pyrophosphate to give uridine triphosphate and glucose-1-phosphate. Kalckar et al. have shown in hæmolysates[3] and in liver homogenates[4] from patients with the disease that it is the enzyme for the first stage, galactose-1-phosphate uridyl transferase, that is missing.

It is useful to know that the enzyme defect may be shown in cord-blood cells immediately after birth, so that in families at risk affected infants may be identified and put on a lactose-free diet from birth. Holzel and Komrower,[5] in 1955, produced evidence that some of the parents, who are themselves heterozygous for the gene responsible for galactosæmia, had an abnormal galactose-tolerance curve. Unfortunately Kalckar and his associates[3] have not been able to detect any abnormality in the amount of galactose-1-phosphate uridyl transferase in parents.

It is a striking example of the uniformity of many biological processes in the animal kingdom that four mutant forms of the bacillus *Escherichia coli* are known with the same enzyme defect.[6] Three other galactose-negative mutants of the bacillus lack instead the enzyme galactokinase concerned in the first step of all—the conversion of galactose to galactose-1-phosphate—but these have as yet no human counterparts.

ATYPICAL ACID-FAST BACILLI

MANY investigators have isolated from patients strains of mycobacteria which, for want of a better name, are called "atypical acid-fast bacilli." These bacilli are not new,[1 2] but in recent years they seem to have been recognised much more commonly. In man they are associated with pulmonary lesions, often serious and progressive, which in every way resemble typical pulmonary tuberculosis[3]; but unhappily their response to most antituberculous drugs is poor.

It is not yet certain whether these organisms comprise a homogeneous group or several different types. They differ from typical tubercle bacilli not only in their drug sensitivity pattern but also in being chromogenic, and in showing greater catalase activity, poor cord formation, a negative neutral-red reaction, and avirulence for guineapigs. Usually they can be distinguished from typical acid-fast saprophytes by a rather slower growth rate, especially at room temperature (though they grow faster than typical tubercle bacilli) and by the type of lesions in certain laboratory animals. Wolinsky et al.[3] found that in each of three cases of infection by these organisms in man, the strains produced orange or yellow pigment; but in two they did so only in light. Crow et al.[4] describe 69 such cases, in which the organisms seemed to fall into three main groups judged by growth on Lowenstein-Jensen medium. In 64 cases the strains produced smooth, slow-growing buff colonies which became orange as the cultures aged; in 3 the strains were more chromogenic but otherwise similar; and in 2 the strains gave rough colonies similar to those of *Mycobacterium tuberculosis* except that they grew much more rapidly—though not so rapidly as recognised acid-fast saprophytes.

Pathologically, according to Crow et al., these organisms give rise to lesions differing in no way from those due to typical tubercle bacilli; but the disease is less readily communicated: in none of their 69 cases was more than one member of a household known to be infected. On the other hand, the response to antituberculous treatment is disappointing: of 56 cases reviewed by Crow et al. only a third showed sputum conversion on chemotherapy.

These studies and others[5–7] make it clear that atypical acid-fast bacilli present a fairly serious problem. It can hardly be doubted that infections with these organisms have become more prevalent since chemotherapy has been widely used; and conceivably they represent mutants induced or selected by chemotherapy —a hypothesis that seems to be supported by the partial resistance of most strains to antituberculous drugs. Thus, incomplete treatment of tuberculosis due to drug-sensitive typical bacilli may carry the danger of fostering these drug-resistant atypical forms, though so far this has by no means been proved. Meanwhile infections with these atypical organisms should, it seems, be treated as are infections with typical bacilli, and, despite their seemingly lesser infectivity, public-health measures should be applied no less rigorously than is usual in tuberculosis.

OF THE SCHOOL OF MEDICINE, UNIVERSITY OF PITTSBURG, PA

Whenever metal is inserted in the human body it becomes subjected to the corrosive attack of the body-fluids Venable et al (1937) drew attention to this phenomenon and suggested that a simple means of reducing the risk of corrosion would be to avoid the use of more than one metal in any particular operation Discussions of the dangers accompanying the insertion of "mixed metals," and descriptions of investigations carried out to discover a metal which could confidently be adopted as standard, have been published periodically throughout the last two decades But, although this work is well known to many surgeons, the recent paper by Cater and Hicks (1956) shows that in some hospitals insufficient attention has been paid to this aspect of surgery Until the basic principles put forward in a series of papers by Venable and Stuck some twenty years ago are clearly understood and accepted (and if necessary protected by an official standardisation of the materials used for implants), there is little point in taking precautions to avoid the secondary causes of corrosion and the possible tissue reactions which can result from them The first step in preventing metallic corrosion in surgery must be the use of a single passive metal for all the components of an implant

The physiological behaviour of the body during trauma and the subsequent healing processes create the environment within which the metal implant has to fulfil its purpose The pH value and the redox potential will vary with time, and also from place to place on the surface of the metal These variations cannot readily be controlled but their effect could be minimised by the careful selection of the particular metal best suited to withstand these electrochemical conditions Clearly the use of two different metals in a region with such a complex electrochemical nature is an invitation to disaster Most metal implants are subjected to mechanical stress when fixed in the body, in many cases there may also be fretting between different components of the appliance Both these phenomena can influence the corrosion of metal, and they too should be borne in mind when selecting the most suitable metal for use in orthopædic surgery It would be dangerous, however, to believe that such a standardisation will solve all the problems created by the use of metals in orthopædic surgery The insertion of "mixed metals" is by far the most important cause of corrosion, but it is by no means the only one The factors which can influence the corrosion resistance of metals have been fully discussed by Evans (1946)

There is clear evidence that even when a single passivated metal is used, a tissue reaction is occasionally observed in the region surrounding the implant, and it is important that the need to select the metal must not obscure the complementary need for proper treatment of the implants both before and during insertion Many metals derive their high resistance to corrosion from an impervious layer of oxide which protects them from the surrounding liquid But such an insulating barrier is effective only so long as it remains intact If it is damaged, corrosion will occur at the places where the metal and the liquid come into contact, the attack will continue unless the product of the electrochemical reaction is insoluble and is deposited at the corrosion site, thus making good the protective coating

The special characteristic of stainless steels is that they are clothed in a protective film which in normal circumstances is self sealing In this respect they differ from the noble metals which are intrinsically inert It is clear that the selection and use of a stainless steel will be vitiated if, during the operation, the passivating surface film is so damaged that the sealing process cannot re-form the protective layer before continuing corrosion is established Any treatment which increases the chance of a breakdown in the passivity of the metal ought to be avoided whenever possible, and especially during the operation The manner in which the implants are handled can have an important influence on their subsequent chemical behaviour

The importance of the correct choice of tools should be appreciated Experiments using radio-isotope techniques have shown that during an orthopædic operation small fragments of metal are plucked from the surface of the tools and become welded to the implant These particles from the tool are buried with the appliance in the body

The composition of the metal tools is usually different from that of the implant There is evidence that such foreign fragments can initiate a reaction resulting in the corrosion of the buried metal Analytical evidence supports this view the concentration of metal ions in the tissues surrounding parts of the implant which have been handled by tools are many times higher than normal, even when there is no visible sign of corrosion or tarnishing whereas the concentration in the tissues adjacent to unhandled parts of the same appliance are normal A full account of these experiments has been given by Bowden, Williamson, and Laing (1955)

It has been suggested (Capener 1956) that surgeons and manufacturers should have official guidance in their choice of suitable metal for implants It might be useful if this included recommendations on the methods of handling the implants, and on the nature and composition of the tools used for inserting them, so that their corrosion resistance shall not be needlessly impaired

PROFESSIONALISM AND BUREAUCRACY

In his Winchester Address, given on May 15 under the auspices of the Winchester division of the British Medical Association, Mr Graham Hutton began by considering what has been happening in all kinds of human societies during "this terrible but exciting 20th century"

THREEFOLD CHANGE

1 *Technical*—The techniques of control over Nature have immeasurably multiplied and accelerated, and it is good that human powers over inhuman powers are being so rapidly increased But it is bad that increased human power is used—or abused—to stress human beings beyond their normal tolerances, or to frustrate their natural modes of expression and development, or to compel them to behave as machines

2 *Political* —Whereas the course of last century all over the world, was liberal, in humanistic terms, the course of the 20th century has been towards more and more collective restraint of individuals Everywhere the State has steadily increased its power over individual lives, and in almost every walk of life Because of the first or technical change, this second or political change has brought benefit to millions in many nations it has permitted the removal of old evils But, both in democracies and in dictatorships, power over the individual and the family has been concentrated in a more and more centralised form of State apparatus

> "We realise that in our own country and society today economic, professional, trade union legal, travel, and other freedoms are not what they were They are narrower, not at the administrative centres of these sectors of life, but on the periphery where the individual members live and operate Even apart from, and under the centralising political power of the State, these other sectors of individual life—in business, trade unions, professions, vocations, sport, commercialised pleasures and leisures, and media of publication and radio communication—are all of them more centralised, more collectively organised in larger administrative units "

As the first or technical change has shrunk the whole world and crammed the human race cheek by jowl, so has the second or political change unfolded everywhere—the concentration of vastly enhanced social or political power in the hands of the few, and the once vaunted "rule of Law" has given way everywhere to the contemporary rule of laws and regulations affecting more and more of individual life

3 *Specialisation* —The third change is an ever-deepening, ever narrowing specialisation which further weakens the powers, potentials, and freedoms of the citizen The individual—learner, researcher, operative, technician, professional man, trade unionist, or manager—sees his own mastery of only a little part of a widening field becoming smaller and smaller, and himself becoming ever more dependent upon the results of other people's work, which he cannot understand or control

So universal is this third change in mankind's social process that precisely the same kind of complaints about it arise in America, in Russia, in India, in Africa—in school and university and other training curricula, in religions, castes, social classes, income brackets of all levels, and so on The burden of complaint is the same—that distinguishing individualities are tending to be ironed out, that differentials and varieties are being flattened, and that frustration of human potentials follows specialisation Then, through such frustration, bad social outbreaks occur the system of law and custom rights and duties, sentiments and beliefs and values begins to lose its binding force Either as individuals or as functional or other groups, men begin to rebel, to become "anti minded," against their own society Today this phase—the era of social revolution—is world-wide for the first time

RUSSIAN LABORATORY

Perhaps the most significant event of the post war era, Mr Hutton thought, will prove to be the working out of these revolutionary social changes in Communist Russia Western and other countries can learn much from what has happened inside the Russian social laboratory during the past decade or two

At its beginning forty years ago, Russian society was dedicated to equality, and it soon took away all powers and privileges of trades unions, professions, vocations, and other self governing voluntary and functional groupings But because of the technical needs of all society everywhere (in our time as in Plato's) a new set of groupings, orders, castes, classes, and functional elites speedily came about—nearly all of them necessarily organised on the lines of the former professional and other functional groups As modern techniques advanced—in economic science, medicine, the arts—it was the *professions*, not merely the State's agents or functionaries, who gathered esteem, powers, and privileges

One feature of the convulsions in Russia and other Communist lands during the past three years needs to be noted for its long term significance It is that the uprush of protest against flattening and standardisation by the omnipotent State, against unqualified egalitarianism, and against the tyrannies of an all pervasive bureaucracy have occurred in the ranks of the experts—the people with long-acquired and long-trained vocations whom a modern society needs more and more It is among this younger generation of Communists—among the experts and artists, the technicians, and the professional persons above all—that the ferment of dissatisfaction with the bureaucracy is greatest

DIFFERENTIALS

"At both the superficially seeming opposite poles of world politics today, in North America and in Soviet Russia, really substantial differential rewards for differential responsibilities and differential expertnesses are the order of the day," said Mr Hutton, "while here in British society, which is lagging behind those in material progress and mixed-up between them in its social and political organisation, our skilled workers moan about the erosion of their 'differentials' in wages, the salaried folk can complain of the same process, and the folk of technical prowess and professional responsibility are the most savagely penalised and discriminated against of all"

The material sacrifices due to the last war have fallen, net and on balance, upon only about one fifth of the British people, which includes three twentieths who are the old and retired at all levels of income (some very poor and on National Assistance) and all the skilled, trained, and responsible paid leaders of the nation Just as an examination and a justification of equality of treatment for everybody is long overdue in our political and social system, so is an examination of the distribution of rewards for responsibilities "Somewhere around the current figure of £1000–£1500 a year gross for a bread winner—no matter what his training or responsibilities, or how big his family, or what his hours of work or conditions of service—British society seems to shut up shop in consideration of him"

Looking at the needs of medicine, of the expanded atomic energy programme, of the highway and railway networks, of slum clearance, of education in all its forms, and of new equipment for all our industries, "we shall better appreciate our overriding need not to penalise, but positively to stimulate and increase differential rewards for, any and every citizen who can command such enhanced rewards in virtue of his abilities, responsibilities, and social contributions"

> "What we have undergone in the past eleven post war years, in a world of technical revolution, has merely been a revolution in the apparatus of the State and in its administration We have had no post war revolution of thought and ideals and imagination"

THE PROFESSIONS

If British professional bodies are to play their part in the reshaping of our people's thought and the reform of our national institutions, they must first be sure that on balance what they propose to do will primarily benefit the community or communities they serve

> "The justification for a profession, which guards its own standards of training, can only be that in so doing it constantly proves its contributive power to the community is kept at top pitch Any profession will lapse in public esteem if either it fails to do that, or fails to make public why the State or some other factor beyond its power prevents it from doing it

The great power of our professions still resides in their vocational mission, their safeguarding of training and education, and their rôle—quite apart from their particular skills—in turning out the well rounded, socially adjusted, contributory and responsible leaders of the nation in all its walks of life It is perhaps this last rôle which is so often overlooked in our land today Without wise leaders, without a widely trained and humanistic élite, any society on earth, both today and in the even more technical complexity of the future, will perish It is as much the function of our professions—and pre eminently of yours—to turn out members of such a national elite, as it is to turn out technically qualified young men who are certified as able to perform certain skills adequately The professions would gain, I think, if they were to emphasise that aspect, in season and out of season, and, above all, if they were to see, in their educational curricula which still remain largely under their own safeguarding, that they did not merely turn out technically adequate young men, but young men who were in addition humane, rounded, and adjustable to a rapidly changing social context "

Contemplating the hectic experimentation in North America at one extreme and in Russia at the other, we need not (concluded Mr Hutton) despair or repine Technically it is well within our scope to succeed, in any sector of social life, as well or better There is no economic reason why we should not But if we bring it off, it will primarily be due to leadership, and that must still come largely from our professions "It is therefore up to them to set their own standards, and then to fight for them until they prevail There is nothing wrong in that for the nation On the contrary, I think this nation has everything to gain from it "

REGIONAL HOSPITAL BOARDS
AND BOARDS OF GOVERNORS OF TEACHING HOSPITALS

THE Minister of Health has appointed, or reappointed, the following as chairmen of boards New appointments are indicated with an asterisk

Leeds Regional Hospital Board —Major J C Hunter, M C

South West Metropolitan Regional Hospital Board —A G Linfield, O B E, J P

Oxford Regional Hospital Board —Sir George Schuster, K C S I, K C M G, C B E, M C

Birmingham Regional Hospital Board —* E W Thompson, M A, J P

United Newcastle upon Tyne Hospitals —* Sir Walter Drummond

United Leeds Hospitals —Sir George Martin, K B E, LL D, J P

United Sheffield Hospitals —Alderman A Ballard, C B E

United Cambridge Hospitals —Roger H Parker, M C, D L, M A

United Oxford Hospitals —Sir David Lindsay Keir, M A, LL D

United Cardiff Hospitals —Alderman Thomas Evans, C B E, J P

United Birmingham Hospitals —Evan A Norton, M A

St Bartholomew's Hospital —Sir George Aylwen

London Hospital —Sir John Mann

University College Hospital —Sir Alexander Maxwell, K C M G

Middlesex Hospital —Lord Astor of Hever, D LITT, J P

Charing Cross Hospital —Lord Inman, P C, J P

St George's Hospital —Viscount Ingleby

Westminster Hospital —Lord Nathan of Churt, P C, T D, F S A, D L

St Mary's Hospital —Edgar E Lawley

Guy's Hospital —Lord Cunliffe

King's College Hospital —Marquess of Normanby, M B E

St Thomas's Hospital —Sir Arthur Howard, K B E, C V O, D L

Hammersmith, West London, and St Mark's Hospital —Sir Desmond Morton, K C B, C M G, M C

Royal National Throat, Nose and Ear Hospital —Ernest Taylor

St John's Hospital for Diseases of the Skin —J A M Ellison Macartney

The Hospitals for Diseases of the Chest —Sir John Gilmour

Royal National Orthopædic Hospital —Sir Henry Floyd, C B, C B E

National Heart Hospital —J M Oakes, M C, D L, J P

St Peter's, St Paul's, and St Philip's Hospitals —Laurence Bevan

Royal Marsden Hospital —J M Wallace

REGIONAL HOSPITAL BOARDS

The following doctors have been appointed or reappointed to the boards They will hold office till March 31, 1960

Newcastle —C N Armstrong, R E Jowett, R S Venters

Leeds —W A Hyslop, G Whyte Watson

Sheffield —G H Gibson J L A Grout, C S O'Flynn

East Anglia —A Leslie Banks, K J Grant

North West Metropolitan —E C Warner, Katharine Lloyd Williams, *F C Wilkinson

North East Metropolitan —T Rowland Hill, J Arthur Moody, R W Reid

South East Metropolitan —Sir William Kelsey Fry, V F Hall, W G Masefield, * H W L Molesworth

South West Metropolitan —A Lawrence Abel, Sir Geoffrey Todd

Oxford —C V Gledhill

South Western —R J Brocklehurst, L C Hill, A V Neale

Wales —J P J Jenkins, A Trevor Jones, Emyr Wyn Jones, E K Roy Thomas

Birmingham —J H Sheldon, A P Thomson

Manchester —V F Lambert, R W Luxton, Miles Parkes, Sir Harry Platt

Liverpool —W M Frazer, H L Sheehan

BOARDS OF GOVERNORS

The following doctors have been appointed or reappointed to boards of governors They will hold office till March 31, 1960

St Bartholomew's Hospital —Charles Harris, J Basil Hume, E G Tuckwell

London Hospital —J Graham, G T Hankey, * William Evans, * Dorothy Russell

Royal Free Hospital —Gladys Hill, Katharine Lloyd Williams, Margaret MacPherson, * Una Ledingham

University College Hospital —Sir George MacRobert, Wilson Smith, * Sir James Kilpatrick

Middlesex Hospital —* A J B Goldsmith, * C A Keele, * B R M Johnson, * D H Patey

Charing Cross Hospital —D H Campbell, E Grundy, H G E Williams, * Norman Tanner

St George's Hospital —C Bowdler Henry, Rodney Smith, * H W Gordon

Westminster Hospital —A Lawrence Abel, H E Harding, Edward Stanley Lee, R J V Pulvertaft

St Mary's Hospital —A G Cross, Robert Cruickshank, G B Mitchell Heggs, Leonard Simpson, * Denis Brinton, * W D W Brooks

Guy's Hospital —Maurice Campbell, Sir William Kelsey Fry, * G F Gibberd

King's College Hospital —H L Glyn Hughes, Sir Cecil Wakeley, * Wilfrid Sheldon

St Thomas's Hospital —T Pomfret Kilner, Sir Max Page, A J Wrigley

Hammersmith, West London, and St Mark's Hospitals —R Cove Smith, Sir Allen Daley, Cuthbert Dukes, Sir Francis Fraser

Hospital for Sick Children —G H Newns, Bernard Schlesinger, D Innes Williams, * R E Bonham Carter, * J A Scott

National Hospital for Nervous Diseases —Sir Russell Brain, J St C Elkington, M Kremer

Royal National Throat, Nose and Ear Hospital —J C Hogg, G H Howells, * T V L Critchlow

Moorfields Hospital —* G G Penman

Bethlem Royal and Maudsley Hospitals —C P Blacker

St John's Hospital for Diseases of the Skin —Janet Aitken, S Cochrane Shanks, * L Forman

Hospitals for Diseases of the Chest —Sir Russell Brock, J L Livingstone K Robson, Vernon Thompson

Royal National Orthopædic Hospital —C H Lack, R Nassim

National Heart Hospital—H A Bulman, * T F Cotton

St Peter's, St Paul's, and St Philip's Hospitals—A R C Higham, * H G Hanley

Royal Marsden Hospital—P E Thompson Hancock

United Manchester Hospitals—W I C Morris, Sir Harry Platt, * J F Wilkinson

United Liverpool Hospitals—W M Frazer, C A Wells, * E Wyn Jones

TERMINOLOGY OF HEREDITARY HÆMOGLOBINOPATHIES INVOLVING HÆMOGLOBIN VARIANTS

THE Colonial Medical Research Committee's Working Party on Sickle-cell Trait and Sickle-cell Anæmia * has issued the following recommendations which, it says, are based on immediate practical requirements rather than on fundamental theoretical considerations, and are put forward at the present time solely with the aim of discouraging the growth of ambiguous systems of terminology until an agreed international system has been devised

General

(*a*) The term " sickle cell disease " should be used to denote any pathological condition which is, in part, attributable to sickling of the red cells The term " sickle cell anæmia " should be reserved to denote the presumably homozygous state Its use is (strictly) conditional upon the demonstration of homozygosity from family studies

(*b*) Fœtal hæmoglobin is excluded from the present discussion of terminology, though its persistence in varying degree is an often observed feature of states involving the hæmoglobin variants Statements regarding its occurrence should be made as part of the biochemical findings

(*c*) The Working Party appreciates the desirability of having a complete statement of the Hb variants actually present, preferably in order of decreasing proportions, leaving the clinician to decide if an actual (or potential) pathological situation needs to be described, and the geneticist to state how the observed combination of Hb variants has arisen The Working Party also appreciates the undesirability of using a terminology with genetic implications in the absence of family studies

(*d*) The term " hæmoglobinopathy " should be used to denote a condition in which the production of normal adult hæmoglobin (Hb–A) is partly or wholy suppressed and it is partly or wholly replaced by one or more hæmoglobin variants, which may include fœtal type hæmoglobin (Hb–F)

Specific

(*a*) The term " sickle cell should be hyphenated when used as an adjective

(*b*) Excluding Hb–F from consideration, the biochemical state involving Hb–A and any other one hæmoglobin variant (Hb–X) should be described as Hb–X trait "

(*c*) The term " disease " and not the term " anæmia ' should be used generally to denote pathological conditions associated with hæmoglobin variants

(*d*) The term thalassæmia " should be retained because the genetic variants of thalassæmia present themselves as such These variants should be described as ' Hb–C/thalassæmia " Hb–E/thalassæmia,' &c The term " thalassæmia ' should be used rather than the terms " Cooley s anæmia " " microcythemia," &c The qualifying terms " major " and " minor ' are in practice used to denote the presumably homozygous and heterozygous states respectively, but their use in this way is (strictly) conditional on supporting evidence for the nature of the genotype from family studies

(*e*) A morbid condition, not presenting itself as sickle-cell disease or as a variant of thalassæmia, but produced by any one or two Hb variants, in the absence of Hb–A, should be described as a " disease "—e g, " Hb–C disease," " Hb–C/Hb–D disease " (hypothetical) It is appreciated that some of the possible combinations are not yet known to produce morbidity in adults

Examples of Known Hæmoglobin Combinations

A	Normal adult
A + F	Infants
A + F	Thalassæmia
S + F	Sickle-cell anæmia
A + S	Sickle cell trait
A + S + F	Sickle cell/thalassæmia
C (+ F)	Hb–C disease
A + C	Hb–C trait
A + C + F	Hb–C/thalassæmia
S + C (+ F)	Sickle cell/Hb–C disease
D	Hb–D disease
A + D	Hb–D trait
S + D (+ F)	Sickle cell/Hb–D disease
E (+ F)	Hb–E disease
A + E	Hb–E trait
E + F (+ A ?)	Hb–E/thalassæmia
G	Hb–G disease
A + G	Hb–G trait
A + I	Hb–I trait
A + H	Hb–H trait
A + J	Hb–J trait

In the above examples, the hæmoglobin variants given in parentheses are not always found

---

* The members of the Working Party are Prof A W Woodruff (chairman) Dr A C Allison Prof P C C Garnham Dr H Lehmann Dr F Lawthwaite Prof B G Maegraith Dr A E Mourant Dr A B Raper Dr J C White and Dr G H Beaven (secretary)

Public Health

Health in Scotland

LAST year in Scotland the infant mortality rate fell to the lowest level on record and there was evidence of continuing gain in the health of children (in Glasgow and Edinburgh, boys aged 13 in 1955 were a stone heavier and 4 inches taller than the boys of 1913), but the death rate in men aged 45–64 increased slightly [1] In this group the dangers were from lung cancer, bronchitis, and heart disease—particularly coronary thrombosis, which was responsible for 15 6% of all deaths Physicians and surgeons had a death-rate from coronary thrombosis 73% above the average, and other professional and managerial groups had similarly high rates An interesting table in the report on the year compares the death rates from cancer at various sites in 1931–35 with those in 1953–55 At most sites the rates were about the same in the two periods At some (especially the lymph glands) there was a fall, at others (such as the urogenital tract in men, the cervix in women, and the pancreas in both sexes) a slight rise, but in the lung (including trachea and bronchi) the rate had risen threefold in women and sevenfold in men In the brain the rises were surprisingly high—ninefold in women and twelvefold in men—and this is attributed in the report to better diagnosis

The report emphasises that simple trends of death rates have lost some of their significance as indices of the nation's health, and more account should be taken of sickness and disablement, though information here is insufficient The greatest losses of time from work were caused by respiratory tuberculosis, psychosis and neurosis, bronchitis and pneumonia, and rheumatism A two year mass radiography campaign is now in progress

The numbers of hospital admissions and discharges, of bottles of blood transfused, of outpatient attendances, and of nurses employed all continued to rise Eight major hospital schemes were under construction Voluntary admissions to mental hospitals numbered 6587 (compared with 3975 in 1950) The report express-concern at the rise in the number of prescriptions for phenobarbitone (2 million, or over 10% of all prescriptions) and other sedatives, and in the number of deaths *attributed to such drugs (77, compared with 18 in 1948)* Some of these deaths were suicidal, some accidental Accidents continue to be a major cause of death and disability, in 1955, 192 babies under a year died by accident and only 35 from all infectious diseases (including tuberculosis but not pneumonia) There are many more serious accidents at home than at work or on the roads, in 1950–55, 48% of the fatal accidents in males and 85% of those in females were at home In 1955 there were 1120 deaths in Scotland from home accidents, besides many severe injuries Most of the fatalities were in children under 5 years or people over 65 The biggest hazards for the old were falls and accidental gas-poisoning, for infants, suffocation (in bed or by inhalation of food) Deaths from burns and scalds, and from poisoning by solids and liquids, were next in order of frequency If anything, the accident-rate was increasing, and it is good to learn that research on these matters is being done in Scotland, and that home accidents are "now regarded as a problem within the sphere of local authorities"

---

[1] Report of the Department for Health for Scotland 1956 H M Stationery Office Pp 147 5s 6d

Poliomyelitis

In the week ended May 11, uncorrected figures for poliomyelitis notifications were (previous week in parentheses) paralytic 39 (35), non-paralytic 30 (25), total 69 (60) The figures remain well above the seasonal average From 1948 to 1956 the highest previous total for the corresponding week of the year was 36 (in 1953) The total number of cases this year (up to and including the 19th week) is 825, the highest corresponding figure in 1948–56 was 649 in 1950 Last year the total at this stage was 480 The districts particularly affected include Barnet (66 3 cases this year per 100,000 population), Stevenage (49 9), Colchester (43 6), and Tendring (near Colchester) (40 7)

Suspected Smallpox

A soldier stationed at Perham Down, Wiltshire, has been taken to an isolation ward in Reading because he may have smallpox[1] The unit affected is the 39th Heavy Regiment, Royal Artillery 8 men who had been living in the same room are in an isolation ward in the camp and between 400 and 500 men of the unit are confined to camp for revaccination Reports suggest that the soldier has not been abroad recently

More Dental Decay in Children

In his report for 1956, Dr R G Davies, principal school medical officer for Huddersfield, speaks of the "very regrettable" increase in the incidence of dental decay among younger children With a decrease, or the possibility of a decrease, in the number of dental officers, he added, it was easy to see that restorative dentistry would not be able to cope with this trend if it continued The solution would have to be found not in extractions or even in conservative treatment but in some means of preventing dental decay Unless methods such as fluoridation proved a short cut, the only answer lay in the education of parents and children in the prevention of dental disease

B C G Vaccination

The Research Defence Society has produced a pamphlet[2] setting out the answers to the questions that most parents ask about B C G vaccination The pamphlet explains why and how vaccination is performed in this country and says firmly, in assessing the vaccine's effectiveness, "it is no longer possible to doubt the usefulness of B C G vaccination" Questions are also answered about the preparation and safety-testing of the vaccine

In England Now

A Running Commentary by Peripatetic Correspondents

It is odd that, though there are universities, postgraduate schools, lecturers, and textbooks galore devoted to the training of a consultant, there is no theoretical training for the thorniest obstacle of all—the selection committee's interview Fortunately benevolent officialdom has recognised this, and supplies unlimited practical experience

Thus, everyone knows that the post of consultant *omphologist to* Slumtown will *go* either *to* Bloggs, aged 43, with seventeen relevant letters after his name, and who has written two books, or else to Snooks, aged 41, with only fourteen letters and one book to his credit, but who is well favoured locally, and thought to be a promising young man Despite this, McGregor, Smith, Jones, and O'Hara, mere striplings in their late 30s, will be summoned from the four corners of the *kingdom* They will be senior registrars, usually laughingly called "transitional," and though they spend the rest of the year on an income which keeps them a bare fraction from the breadline, officialdom suddenly pretends *to* believe that *they* lead a champagne-and-caviare existence, and would refuse to come unless brought first-class So there they are in their best blue suits, only distinguishable by the slight fraying at the cuffs from all the other people who travel first-class on expense accounts

At the interview the questions are as unchangeable as the signs and symptoms of appendicitis, so that there is plenty of scope for textbook coverage "What interests have you outside medicine?" "As an omphologist, what do you consider should be your relations with the Xiphisternist?" "Is there any particular branch of omphology in which you are interested?" and so on These questions are so standard that publication of an unusual one would be as interesting as the report on a case of nagana on St Kilda The taxpayer would be saved a lot of money if this routine information were available in print, but until some enterprising author appears, we shall have to continue our little trips, even though we are only 37 and have a bare eleven letters *to our name*

* * *

Why don't I keep my big mouth shut? Since birth I have been 100% tone-deaf my nursemaid winced at the discords, the kindergarten mistress asked me not to sing in the carols, the French master tore his hair All in vain, Hi-Fi is lost in the ataxic cilia of my cochleæ Consequently all foreign languages are beyond me I haven't a clue what all those mouthings mean without the explanatory *manual* gesticulations Thank Heaven most of the world speaks English and seems to get a kick out of airing it to provide my material comforts But when in Rome, or Stockholm, or Oslo, I really do try to merge into some of their less *exotic* background habits. On a visit to a large camp of young people I was invited to dine at the top-table on the first evening With punctilious courtesy we stood behind our chairs until the whole company was assembled in the dining hall The Commandant gave three sharp raps on the table with his knife, and spoke a couple of dozen words in Norwegian Everyone bowed their heads and looked most solemn I said "Amen" rather loudly and sat down It seemed the obvious way of joining my hosts in spirit, but the top-table looked distinctly startled For want of anything better as an opening conversational gambit, I leaned across to our interpreter and enquired if the *Commandant's* words were the usual form of Norwegian grace When the howls had died down, I gathered the horrible truth of his translation 'If you want any beer you must buy it yourselves"

* * *

Samples of the latest tranquilliser reached Singapore, appropriately enough, the same day as the news of the success of the Singapore "Merdeka" Mission to London They lay on my desk until Maundy Thursday when I packed my bag for the annual general meeting of the Malaya branch of the B M A, held this year in Kuala Lumpur

The journey north was delightful and we made excellent time until we reached a check point at Gemas, at the beginning of one of the "food denial areas" which have been so successful in starving the bandits out of the jungle Here I reported I had two apples, but was prepared to jettison them if they were prohibited No, a reasonable quantity of fresh fruit was permitted, but could I please produce them for inspection? I opened my bag, but most of my interest was taken up by the very thorough examination of the car in front where a tin of sardines had just been produced in triumph from under the hubcap of a rear wheel My attention was drawn back sharply to my own bag when the examining Gurkha soldier asked "What is this?" holding out the samples I'm not an expert Malay scholar at best, and in any case I doubt if even the director of the new Agency for Malay Language and Literature has got round to inventing a Malay word for "tranquilliser" yet, so I told him it was headache medicine A conference was held with a Malay policeman and a Malay civilian and they became so grave that even the finder of the tin of sardines seemed to think that his success had been eclipsed

[2] B C G Vaccination Against Tuberculosis Conquest pamphlet no 2 Price 3*d* from the Research Defence Society, 11 Chandos Street, Cavendish Square London W 1

The inevitable Job's comforter in the car behind told her companion in a loud voice about a friend of hers who had been fined $500 for having "been caught with a bottle of aspirin," and that "everyone knows that the Communists in the jungle are very short of drugs" My visions of a happy Easter weekend with my colleagues were fading Then the Gurkha said "Ini obat banya sallah, Tuan" I translated this literally as "This is very bad medicine, Sir" and was prepared to agree, abandon it, and go on my way, but apparently it was the possession of it without a permit that was so serious I had to be taken before the assistant district officer to have my fate decided

A long interview followed in which I was able to establish my identity as a medical practitioner by the production of a number of passes which authorise me to enter military areas and the harbour board area, and to inspect houses and buildings under the municipal ordinance, which I had regarded for years as nuisances because they clutter up my wallet and were never required Finally I was given a "Permit for the Movement of Goods between the hours of 6 A M and 7 P M" with everything on it deleted except item 17 "Drugs," and that was endorsed "2 Packets Samples"

This is my first experience of tranquillisers, and, as far as I am concerned, they did their best to upset the tranquillity of a lovely day I was careful to dispose of them before setting out for the return journey to Singapore

* * *

A discussion of the French cave-paintings led me to undertake a small study of wall-work in the West Virtually everybody has come to this fast-growing Calgary from some other place, and where local roots seldom go deep the citizen is rare indeed who can say that his grandfather was born here Therefore walls carry material that indicates the origins, ambitions, and masonic degrees of the people In this land where everybody can read-and-write but so few can truly read, it is plain that little Johnny will go far when his parents have posted by his bedside the certificates of progress at school from grade 1 to grade 2, and then that from grade 2 to grade 3 Only the other day I visited a small boy who lay in a big bed, at the head of which I saw the neatly framed certificate of the marriage of his parents

I am devoting a special section of my study to the offices of doctors In a Province where the Pioneer is a man of such stature in the community that he is almost a Senator, the sign of special note in the offices of the small and diminishing number of doctors who were here before the establishment of the Province in 1905 is the arms of the North West Territories on the *diplomas of* registration with the College of Physicians and Surgeons of pre-history On the other hand a non-pioneer doctor of my acquaintance shows to the world, by means of a small certificate on his wall, that he once attended a course in field hygiene with the R C A M C, and another has put up the citation of a mention-in-despatches during the campaigns of a decade and a half ago

Letters to the Editor

STEATORRHŒA AND HYPOPARATHYROIDISM

SIR,—Dent et al[1] have recently noted secondary hyperparathyroidism in cases of osteomalacia caused by steatorrhœa, confirming Albright's view[2] of the relationship between the two conditions But there may be a connection between steatorrhœa and *hypo*parathyroidism Steatorrhœa usually causes a deficient absorption of phosphorus as well as calcium, and this may lead to a lowered serum-inorganic-phosphate level and osteomalacia The elevated serum-phosphate reported in other cases of steatorrhœa is, therefore, unexpected and needs an entirely different explanation

Bennett et al[3] described the syndrome of "idiopathic steatorrhœa" and remarked that in 5 of their 15 cases the serum phosphorus was above 5 mg per 100 ml, in 1 case it was 6 3 mg They offered no explanation, beyond the unqualified remark that secondary hypoparathyroidism might have been present

Colin Williams[4] reported a case of idiopathic hypoparathyroidism in a boy of 6 years with papillœdema and generalised moniliasis Steatorrhœa became apparent at the age of 5 Tetany with low serum calcium developed a year later when the serum phosphate reached 10 mg per 100 ml There was a good response to parathyroid hormone (Ellsworth Howard test) The duodenal juice contained normal amounts *of trypsin Renal functions were unimpaired Rickets* did not develop and the serum alkaline phosphatase was estimated to be 10 Bodansky units The patient's brother was said to suffer from the "cœliac syndrome"

Lowe et al[5] reported the findings in a young girl who had tetany from birth with low serum calcium and a high serum phosphorus level (up to 7 mg per 100 ml) She had steatorrhœa (with only 65% fat absorption) associated with anæmia, ecchymoses, increased prothrombin time, raised alkaline phosphatase, and low serum vitamin A Pancreatic enzyme production was apparently depressed, but aspirated duodenal juice was normal when the test was *repeated later* There was no response to injection of an active preparation of parathyroid hormone On the other hand there were none of the specific skeletal abnormalities associated with pseudohypoparathyroidism *Ectodermal dystrophies, of the variety* produced by prolonged hypocalcæmia, appeared later

Liefer and Hollander[6] reported the case of a man of 20 who had had idiopathic hypoparathyroidism for ten years, and "diarrhœa" for eleven years They diagnosed steatorrhœa (no fat balance data are given), with normal vitamin A tolerance, normal glucose tolerance, and normal pancreatic enzymes The serum inorganic phosphorus in several estimations lay between 5 and 12 mg per 100 ml The response to parathyroid hormone was good The urine calcium output was around 200 g in twenty four hours, with a serum calcium of only 5 9 mg *Salmonella panama* was isolated from the patient's stool and biliary tract Addison's disease developed later

Salvesen and Böe[7,8] *describe a boy of* 8 who had had moniliasis of skin, nails, and mouth from the age of 6 months He had steatorrhœa, with 82 g of fat in a single day's stool The serum calcium varied from 5 0 to 8 4 mg per 100 ml and the inorganic phosphorus from 5 45 to 6 5 mg, with a single reading of 10 2 mg Though no further evidence is produced in favour of a diagnosis of idiopathic hypoparathyroidism, the well known association of the *condition with* moniliasis makes this diagnosis very probable *Candida albicans* was isolated from the stool, and moniliasis of the small intestine was suggested as the cause of the steatorrhœa

A patient discussed in a conference [9] had hypoparathyroidism, and no parathyroid tissue was found at autopsy Steatorrhœa was mentioned as an incidental finding

MacGregor and Whitehead,[10] while examining the evidence for two separate parathyroid hormones, remarked on 2 cases of steatorrhœa with tetany and with failure to respond to parathyroid hormone In 1, a man of 30, the serum calcium was 6 2 mg and serum inorganic phosphorus 6 3 mg per 100 ml There were 11 g of fat per day in the stool The intravenous parathormone (Ellsworth-Howard) test was negative, and there was no response to intramuscular parathyroid extract (150 *U S P* units a day for four days)

Our own patient [11] was a woman of 32 with a recent history of steatorrhœa and tetany The serum calcium was initially 6 6 mg per 100 ml She had the signs of idiopathic steatorrhœa (clubbed fingers, anæmia, tetany, abnormal small gut pattern and flat glucose-tolerance curve), but she had a gross deficiency of pancreatic enzymes and persistently raised serum phosphorus (4 1–6 7 mg per 100 ml) The high serum-phosphorus was combined with a low urine phosphorus output, but normal renal glomerular function Later tests proved that there was a greatly increased tubular reabsorption of phosphorus, characteristic of hypoparathyroidism There was no response to an active parathyroid extract (Ellsworth-Howard test), though there were none of the physical stigmata of pseudohypoparathyroidism Later, amenorrhœa (associated with a low urinary excretion of follicle stimulating hormone) and uterine atrophy developed

The association of steatorrhœa with the features of hypoparathyroidism is surely too common to be fortuitous Since either alone can produce tetany with low serum calcium, the combination might easily be missed if not specifically investigated, and hence may well be more common than appears Nevertheless, the cases reported do not produce a uniform picture In some the steatorrhœa is the outstanding condition, with biochemical features of hypoparathyroidism discovered accidentally, in others the hypoparathyroidism is outstanding, with the steatorrhœa apparently of less importance Furthermore, the type of hypoparathyroidism differs in its response to parathyroid extract, though in no case are the characteristic skeletal defects of typical pseudohypoparathyroidism reported Lowe et al [4] suggest that in their case the low serum calcium level led to continued excessive parathyroid hormone production This caused constant stimulation of the renal tubules till these eventually became refractory They adduce no evidence for this hypothesis, which could not account for the hypoparathyroidism in cases with a good response to parathyroid extract

Salvesen and Böe [8] suggest that intestinal moniliasis accounted for the steatorrhœa in their patient Certainly this could not apply to most of the others Analysing 85 cases of "sprue" (i e, presumably idiopathic steatorrhœa),[7] they found that the majority had a serum-phosphorus within the normal range In 22 cases the phosphorus was low, and all these had bony decalcification, in only one was the serum phosphorus abnormally raised (a very different incidence from Bennett's 5 out of 15) They suggest that the serum phosphorus would be expected to be low in all cases, if the parathyroids were responding properly to the lowered serum-calcium Consequently they believe that most patients with steatorrhœa have a relative parathyroid insufficiency, and they suggest that this is due to the malabsorption of some substance necessary for the normal maintenance of good parathyroid activity Unfortunately they produce no evidence for the existence of such a substance As mentioned above, other endocrine secretions have failed in this syndrome—pituitary gonadotrophin in one case, and those of the suprarenal cortex in another Addison's disease and true hypoparathyroidism are occasionally seen in the same patient, quite apart from the condition under discussion

I can think of no good explanation for this association of steatorrhœa with hypoparathyroidism, but believe that it is sufficiently well documented to be considered a definite "syndrome" If all patients with steatorrhœa had their serum-phosphorus estimated, and all patients with hypoparathyroidism had their fat absorption estimated, we might learn more about this "new syndrome"

I should like to thank Prof J F Brock Prof F Forman, Prof G C Linder, Dr R Hoffenberg and Dr E Dowdle for their interest and help and Prof C E Dent for drawing to my attention the case of Salvesen and Böe

SENIOR REGISTRARS AND CONSULTANT APPOINTMENTS

SIR,—Dr Hubble's letter of May 11 is specially valuable in that it throws the limelight on the basic problem of the senior registrars For years it has been one of the objects of the Registrars' Group to show that the ratio between senior registrars and consultants is too high and that this improper ratio has been worked out on a supposed need for competition This has always meant that the numbers in training should be fixed above the estimated needs, no serious thought has been given to the fact that this means delay beyond bearing for many whose abilities match up to the available posts but who seem to exist at the present time only to provide "committee fodder" It would be completely rational to allow only just as many senior registrar posts (in each specialty) as would fill the expected consultant vacancies—based on the assumption that the average senior registrar held his post for the expected four-year period Take then a specialty and imagine that twelve posts are to be advertised in 1937 If in fact there were just twelve fourth-year senior registrars available and if all the appointments were made by one committee on the same day, then truly the last post would be filled by default This sort of situation seems to be envisaged by those who demand competition and wastage In fact no such thing happens, the twelve posts are advertised at intervals throughout the year and by the time the last appointment is made in December, there is a new crop of well qualified men ready to compete on level terms with the last of the original twelve, there may even be some second or third year senior registrars to swell the short list, there may be some in their fifth and sixth years and there may be some university lecturers who have never featured on the senior registrar establishment

There is nothing fixed about an absolute length of training for any individual in any specialty, and there will always be adequate competition to allow a selection committee to exclude anyone who despite the passage of proper time interval does not match up to the job There is now and always has been a clear case for a simple adjustment of the ratio between senior registrars and consultants and the creation of a few more consultant posts at the expense of some senior registrar posts which could then disappear In terms of finance and in terms of specialist work this could almost be a paper transaction within the service, but it would be a move which would bring sanity into the situation and reassurance into the lives of many senior registrars and their families It is not enough, however, that the Minister of Health and his advisers should understand this viewpoint, the drive to appoint more consultants and to adjust the ratio must come through the established consultants who, like Dr Hubble, see the need for extra appointments and are prepared to push what may sometimes be unpopular opinions in this matter If this demand does not come the Ministry will for some time remain unconvinced of the position

I must agree with Dr Hubble, that senior registrar appointments at non-teaching hospitals do not promote professional progress, but only when these appointments are *wholly* at non-teaching hospitals Nothing should be allowed to interfere with the senior-registrar posts where experience is gained both at teaching and non teaching hospitals during the normal four-year *tenure*

Finally, I agree that "assistant consultant" status *should not be contemplated* as a compromise There is no real place for such a post in the National Health Service, and although one can understand the plight and urgency of some of its advocates its effect on their own future and on that of the hospital service as a whole might be disastrous

It would not take much in the way of agreement between the Joint Consultants Committee and the Ministry to set the whole matter to rights with fairness and speed, without prejudice to any other negotiations on pay, conditions of service, or junior hospital staff Those of us whose influence is limited to writing to the journals will wish luck to Dr Hubble and his like as they continue to plug away at committees and colleagues

CHRONIC BRONCHITIS AND SMOKING

SIR,—Dr Harley Williams (May 18) does not like the methods adopted by Dr Lennox Johnston in his efforts to stop people smoking—perhaps Dr Johnston's psychopathology exercise is of little value Personally, I do not like this approach either, but I do raise my hat to his tenacity and enthusiasm

Of all people who should discourage young people from smoking and encourage smokers to smoke less, surely Dr Williams should be a pioneer—can he tell us what he has done and what he hopes to do in this connection ? May I suggest that he would contribute something really worth while if he persuaded many of the consultant chest physicians to set a good example how can these men who see the results of smoking ignore the warnings so blatantly ?

That Mr Dunhill (May 18) is amused at the efforts of those who are trying to discourage smoking is understandable but one of these days the Minister of Health and *his department may be forced to take action* to protect the public from the ill effects of smoking And Mr Dunhill may be less amused when the full effects are felt of a campaign which is now being worked out

Many of us are not concerned with the axe the cigarette manufacturers have to grind , our only concern is the health and welfare of the millions of people who are ruining their health by the pernicious habit of smoking

T W HURST

Standish,
Wigan

Hon Treasurer,
National Society of Non Smokers

SIR,—Your three correspondents, Dr Harley Williams Dr Lennox Johnston, and Mr A H Dunhill, whose letters appeared last week, illustrate the variability of the assessment of the enjoyment of smoking

Mr Dunhill quotes the plain statement that smoking is enjoyable, Dr Harley Williams qualifies this by saying that *to smokers* smoking is a pleasure Dr Lennox Johnston says that his own assessment of the enjoyment of smoking is negative So is mine, and one of the deplorable factors in smoking is that so many smokers overlook the fact that smoking is repugnant to most non smokers It inhibits their attendance, not only at cinemas and theatres where smoking is allowed, but also at more important places, such as scientific meetings, and make even ordinary social relationships rather trying How far the non-smoker suffers medically from the smoker's smoking yet remains to be assessed, but it certainly does not contribute to the non-smoker's joy of living

THE Rh BLOOD-GROUPS

SIR,—To answer the letter of Dr Renton and Dr Hancock (April 27) certain little known facts must first be discussed

Early in our studies on the blocking test [1] we found that highly agglutinable erythrocytes are hard to block, while less agglutinable cells are more easily blocked Accordingly, if the Rh positive cells used as test cells for titrating sera are old, lower titres will be obtained in the agglutination test but higher titres in the blocking test Conversely, more agglutinable erythrocytes, such as fresh cells of type Rh_z, or other fresh cells homozygous for the Rh_0 factor (such as cells of types $\mathrm{Rh}_1\mathrm{Rh}_1$, $\mathrm{Rh}_2\mathrm{Rh}_2$, and $\mathrm{Rh}_1\mathrm{Rh}_2$) give higher titres in the agglutination test, but give lower titres in the blocking-test because such cells are difficult to block

Lack of familiarity with this principle has been responsible for serious errors in medicolegal and anthropological blood grouping work, because the sera available commercially for testing for blood factors rh′ and rh″ are mostly prepared from anti-Rh'_0 and anti Rh''_0 sera, to which anti Rh_0 blocker has been added With very agglutinable cells *the blocking* effect may fail , weak false positive reactions can result and may be misinterpreted

Thus in a recent medicolegal case involving Negroids an expert appointed by the court reported an exclusion involving the factor rh′ In repeat tests, his report could not be confirmed, since the mother, child, and putative father all proved to belong to type Rh_0 Presumably *the two parents* were both of genotype R^0r, while the child was of genotype R^0R^0, and failure of complete blocking of the child's cells gave rise to false positive reactions with the anti rh′ serum, which had been prepared in the usual way by blocking anti Rh'_0 serum In another similar case the putative *father* was type Rh_1 and the mother type Rh_0, but the child's blood gave weak reactions with the anti rh′ serum used for the test This was obviously a false positive reaction since control rh′ positive cells gave much stronger and clearer reactions with the same serum, and repeat tests with antiserum to which additional blocker was added proved that the *baby's type* was Rh_0 instead of type Rh_1, as the preliminary tests seemed to indicate Of course, this pitfall can be avoided by the use of pure anti rh′ sera obtained from type Rh_2 individuals and of pure anti rh″ sera obtained from type Rh_1 individuals, but such monovalent sera are available only in *limited* amounts

Another striking example of mistakes resulting *from this* pitfall is provided by a study of blood type distribution among western Apache,[2] where the following distribution is reported

Rh Hr types	*Number*
CDe/CDe	16
cDE/cDE	4
CDE/CDE	2
CDe/cDE	130
CDe/CDE	47
cDE/CDE	16
CDe/cDe	7
cDE/cDe	6
Cde/cdE	2
CdE/cde	0
Cde/cde	1
Total	231

If these results were accepted literally, one would have to conclude that more than 25% *of the* individuals of this population were carrying the rare gene R^z Now, it is known that in Mongoloids and American Indians the most common gene by far is R^1 , gene R^2 is also present, and *though the* highest prevalence in the world of gene R^z is among Mongoloids, this *prevalence* rarely exceeds 5% Gene r is virtually absent, and almost all *individuals of types* Rh_1 and Rh_2 are of genotype R^1R^1 and R^2R^2, respectively Thus the use of poorly blocked anti-rh′ and anti-rh″ sera could cause a high percentage of these bloods to be misclassified as type Rh_zRh_1 or Rh_zRh_2, respectively I pointed this out in a letter to Dr B S Kraus, in his reply, he admitted the possibility of these errors in the tests, which were carried out in the field under unfavourable conditions

---

[1] Wiener A S *Proc Soc exp Biol* N Y 1944 56 173
[2] Kraus B S White C B *Amer Anthrop* 1956, 58 1017

With respect to the questions raised by Dr Renton and Dr Hancock, our experience has been different from theirs The prevalence of so-called strong D has been much higher than only 5 in 653 If we consider only the rare type Rh_zRh_2 individuals alone, who (as Dr Renton and Dr Hancock admit) almost invariably give strong D reactions, this would already make up 2% for the minimum prevalence of this strong D The discrepancy in our experience might be explained if the bloods tested by Dr Renton and Dr Hancock were not all perfectly fresh After only one or two days' ageing, the blood-cells become less agglutinable so that the strong-D effect could readily be overlooked As I pointed out in a personal letter to Dr Renton, all his pedigree data can readily be explained on the basis of a gene dosage effect For example, the individuals whom he classifies as CDE/cde and cDE/cde seem to be *actually* of genotypes CDe/cDe and cDE/cDe respectively Measuring agglutinability like titrations, is a crude procedure, so variations in the titre may occur due *solely* to limitations of the technique, and this could account for occasional discrepancies in titration scores I should like to emphasise that while the possibility of "strong-D" *cells such as type* Rh^x *(–D–)* or carriers of gene R^{zz} is not denied, the evidence offered by Dr Renton and Dr Hancock was inconclusive, and the fallacious use of genotype symbols to represent phenotypes caused these workers to overlook other possible explanations for their observations

The designations anti-Rh_1 and anti-Rh_2 to which Dr Nicholas (May 4) objects, have not been used for over a decade, so that they can hardly be a source of confusion I am glad, however, that Dr Nicholas has called attention to my book published in 1943, which contains those obsolete symbols, because it also contains the first statistical data refuting the theory of linked genes, which was taken up again two years later by Fisher and Race (Incidentally, publications fifteen years old are not alone in containing ambiguities where C D-E is concerned, *every* current article by C-D-E workers contains errors and contradictions, which increase in number as time goes on)

The justification for the designation "International Rh-Hr Nomenclature" is that these symbols are used by *all* workers, including Fisher and Race, though the latter use the symbols under the transparent pseudonym of "shorthand" symbols

Dr Nicholas's response to my eight questions are not forthright answers It is impossible to acertain, for example, what is his exact position regarding the question of which of the 25 C D-E equivalents for Rh_1rh is the approved one, or what is the position of Fisher and Race regarding linked genes *v* multiple alleles, deletions, &c The difficulty is increased because what the C-D E paradoxers say often does not correspond with what they do In fact, their arguments and position shift as rapidly as a chameleon changes his colour I wonder, therefore, whether Fisher and Race endorse Dr Nicholas's response, or how would they answer my eight questions?

I should like to call attention once more to the tentative report of the committee on medicolegal problems of the American Medical Association, recommending that in medicolegal reports the correct Rh Hr nomenclature be used exclusively, and the C-D-E notations be avoided This report has now been revised, and the final report will shortly be published in the *Journal of the American Medical Association* When preparing this revised report, the committee took into account correspondence received from approximately 50 workers in the field, and could find no valid scientific reason to change the original recommendation This report will reach all practising physicians who depend on the *Journal of the American Medical Association* for an expression of approved standards in medical practice

Brooklyn, New York, U S.A A S WIENER

WILSON'S DISEASE

SIR,—May we comment on your leading article (May 11)? We think your statement that "there can now be no doubt that disordered copper metabolism is the underlying cause" of the disease needs amplification May it not be that the real underlying cause is some inherent biochemical abnormality permitting this disordered copper metabolism to develop? The disease is known to be genetically determined, and it is believed that genes are responsible, not for unit characters, but for unit biochemical processes (Haldane) It would seem justifiable therefore to suggest that hepatolenticular degeneration may be due to faulty genetic control of certain specific protein molecule(s) that normally enter into strong combination with copper, forming cæruloplasmin—the deficiency of which is such a striking feature of this disease The restoration and maintenance, therefore, of normal tissue levels of cæruloplasmin by parenteral administration of this enzyme seems an obvious goal once a supply adequate for prolonged treatment is available A start in replacement therapy of this kind has already been made by Bickel, though a longer period of treatment is necessary before the response can be evaluated The question arises of the disposition and disposal of the intrinsically administered copper, in addition to the problem of removing copper already accumulated, though it is conceivable that, with a sustained normal blood-level of cæruloplasmin, the disordered copper metabolism might readjust itself spontaneously Indeed, balance studies in three of our untreated patients showed an exact equilibrium and not a strongly positive balance, which may argue for a phased activity in this respect

A low serum copper level is not pathognomonic of Wilson's disease, for it may be found in the newborn and in some patients with the nephrotic syndrome Perhaps more significant is our recent finding of subnormal levels in some of the parents of our patients as well as in an unaffected sib, one father had serum-copper and cæruloplasmin levels strictly comparable with those of his daughter who died of the disease It cannot be ignored, then, that some additional factor(s) must co exist which tip the scale, turning a "potential" into an "actual" sufferer from the disease A thorough investigation of parents and families of patients may bring to light some new evidence to account for the anomalous situation now apparent When we can find out what mechanism prevents some individuals with low cæruloplasmin levels from becoming subject to the disease, then perhaps we may be a little nearer helping those not so protected

Considering therapeutic measures, you infer that the earliest possible treatment with dimercaprol (BAL) of biochemically proven cases is likeliest to succeed But, working in collaboration with Bickel (details in the press), we have seen the disease in a young girl progress during three years from the onset of symptoms to death, and at necropsy high tissue levels of copper were found despite protracted regular monthly treatment with dimercaprol, later interspersed with sodium calciumedetate ('Versene') No clinically satisfying improvement was seen in any of the patients we treated with various copper-removing agents, but it may be that the therapeutic attempts were not vigorous enough nor of sufficient duration, though seemingly successful in mobilising copper We found, as did A G Bearn (personal communication), that sodium calciumedetate could safely be given intramuscularly with excellent response, and in some patients the oral route was also effective

We are indebted to Dr P G H Goll for the determination of cæruloplasmin

Birmingham

GILBERT HALL
F C NEALE

CARBUTAMIDE IN JUVENILE DIABETES

SIR,—Dr Engleson and Dr Lehmann [1] found carbutamide (BZ55) safe and useful in children, though Bertram et al [2] observed hypoglycæmic shock when it had been used for a long time

We have tested the drug in 16 patients between 6 and 13 years of age Their daily insulin need before the test period was between 12 and 64 units Carbohydrate metabolism was estimated from blood sugar curves determined before and after every meal, and at 12 midnight and 3 A M

To 3 children with recent diabetes, who had no tendency to acidosis and who had never received insulin, carbutamide was given for eight days in high doses—2 5 g (5 tablets) on the first day, and 1 5 or 1 0 g on each following day No beneficial effect on carbohydrate metabolism was noted

6 patients in full equilibrium with insulin were given, instead of the morning dose of insulin, 1–2 g of carbutamide Their diet remained unchanged The effect was related to the state of the carbohydrate metabolism observed during the insulin therapy

In 2 cases ketosis developed when insulin was stopped, and we were obliged to introduce insulin again In the 4 other patients there was no ketosis, but the drug did not reduce the blood sugar, on the contrary, increases up to 500–800 mg per 100 ml appeared—levels which had never been observed on insulin

In 5 cases we gave 1–1 5 g of carbutamide for five to eight days, combined with a moderate reduction of the dose of insulin Generally, the evening dose was reduced by 4 units to prevent hypoglycæmia at night

In 3 cases ketosis arose between the third and fifth days In 2 cases ketosis did not occur, but a favourable change could not be observed either, and on further reduction of the insulin dose the state became worse

In 4 cases the drug was given together with unchanged doses of insulin (In 2 patients, when the combined therapy had had no effect, the dose of insulin was raised to its original level) In 2 patients the dose was 1 5 g daily, while to the other 2 patients, together with the full dose of insulin, the dose of carbutamide given on successive days was 2 5, 2, 1 5, 1, 0 5, 0 5, 0 5, 0 5 (i e , 9 g in eight days) The drug had no effect on the variations of the blood sugar curve It did not influence carbohydrate metabolism, even in patients who received the drug together with the full dose of insulin

In the course of our experiments it was observed in some cases that in the morning the blood sugar was much under 200 mg per 100 ml, but during the day and at night it was extremely high The beneficial results reported by some observers might be ascribed to their determining only the fasting blood-sugar—i e , in the morning In several of our cases this was considerably reduced Sometimes only traces of sugar were found in the urine but at the same time diuresis was greatly increased, which means that the diabetic state remained unchanged

In our diabetic children the blood sugar level was not reduced by carbutamide, even in full adult doses, and a combination of carbutamide and insulin did not give good results

FIBROSITIC PAIN

SIR,—The concept that fibrositic pain can be caused by localised areas of muscle in spasm—the so called myalgic spots or trigger spots—now seems to be conceded,[1] So too do the contentions that these areas can cause referred pain at a distance and that relieving their state of spasm can relieve such pain

I wish to record a clinical finding which may be of value to general practitioners During 15 years of concentration on the treatment of myalgic spots in the chronic rheumatic diseases, my case records have shown that the great majority of these spots responsible for fibrositic pain—more than 90% of them—are concentrated in a few well defined areas of the body When this is recognised it becomes much easier to locate the offending spots in cases where the source of the pain is not easily apparent

For convenience I have called these areas the "critical zones" There are four of them on each side in the shoulder girdle and two on each side in the buttocks

Critical Zones of the Shoulder Girdle

Zone 1 is the area above the spine of the scapula In my experience myalgic spots in that situation are often responsible for stiff neck, capsulitis of the shoulder joint, tennis elbow, and pain or stiffness in the wrists and fingers

Zone 2 is the area over the shoulder blade below the scapular spine Myalgic spots there can cause severe neuralgic pain affecting the wrists and fingers

Zone 3 is the area along the outer side of the shoulder blade and extending upwards There is commonly a myalgic spot in the upper extremity of the teres muscle, always present in long standing cases of capsulitis

Zone 4 is between the vertebral column and the mesial border of the scapula Though small in extent it may contain myalgic spots responsible for local pain, pain referred to the front of the shoulder joint, spasm of the chest muscles, deficient backward movement of the head, and pain, stiffness, and swelling of the fingers

Zones 2 and 3 are the areas in which myalgic spots can be responsible for Raynaud's phenomenon

Critical Zones of the Buttocks

A line drawn from the great tuberosity of the femur to the sacrum divides the buttock into two main zones

In the upper area, and in its outer portion will be found the spots responsible for pain in the upper part of the thigh, in the sacro iliac joint, and in the ankle joint

In the lower half of this zone may be found the spots causing intense neuralgic pain down the outer side of the thigh in long standing cases of arthritis of the hip joint Commonly they are situated over the tuberosity of the femur

Near the ischial tuberosity there is often a spot responsible for pain or stiffness in the knee joint

Myalgic spots responsible for pain or cramp in the calf muscles and for sciatic pain are often found in the midline of the buttock

London, W 1

LOUIS MOSS

NORMALITY OF AGEING

SIR,—Apropos Dr Rudd's article of May 4, I commend to your readers the following passage from Castiglione's *Il Cortegiano*, translated by Sir Thomas Hoby as *The Courtier* (Mine is the 1937 edition)

> "Old men commend the times past, and blame the times present, dispraysinge our doings and maners, and whatsoever they did not in their youth
>
> "The cause therefore of this false opinion in olde men, I believe (in mine opinion) is, for that, yeares wearing away, carry also with them many commodities, and among other take away from the bloud a great part of the lively spirites that altereth the complexion, and the instruments waxe feebly, whereby the soule maketh her effects
>
> "Therefore the meek flowers of delyte vade away in that season out of our harts, as the leaves fall from the trees after the harvest, and in steade of open and cleane thoughts, there

ATHEROSCLEROSIS IN THE BANTU

SIR,—In his letter of April 13, Dr Annand stated that the Bantu of South Africa are relatively free from atherosclerosis That this belief is fairly general is suggested by an editorial in the *South African Medical Journal*[1]

Such a view conflicts with the few satisfactory post-mortem records that do exist Possibly the most satisfactory of such records are those of Becker,[2] who stated that "the incidence of atheromatosis in the ascending period of life in the Bantu and Coloured subjects (of South Africa) is not far removed from that in other races, the incidence of the senescent type may be slightly less" Our findings are similar to those of Becker and we propose shortly to publish our records

It seems wrong, therefore, to claim that the relative freedom of the South African Bantu from coronary-artery thrombosis is attributable to a relative freedom from atherosclerosis We feel that one likely explanation for this relative freedom may be found in the changed physical and chemical characteristics of the Bantu blood, which in turn may be linked with some abnormality of liver function

Department of Pathology,
Edendale Hospital
Pietermaritzburg, Natal J D WOODS
W LAURIE

PRIMARY HEPATIC CARCINOMA

SIR,—In your annotation of April 6 you claim that the incidence of primary carcinoma of the liver, judged by necropsy findings, has increased distinctly in recent years In support of this statement figures from the Mayo Clinic are quoted—to wit, in 1926 the frequency was 0 083% of 5976 necropsies, contrasted with the finding in 1947 of 0 19% of 16,303 necropsies

Applying the χ^2 test to the incidence-rates and the number of necropsies it can be shown that the absence of a real difference between the given rates of 1926 and 1947 has a probability of more than 7% In addition, the true incidence of a disease cannot be properly represented by necropsy material Therefore, it appears that the quoted figures do not justify the conclusion that the incidence of primary carcinoma of the liver has increased

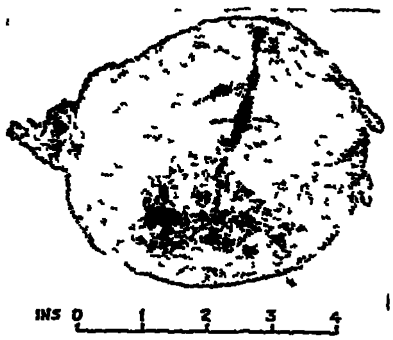
RUPTURE OF THE PREGNANT UTERUS

SIR,—Mr Higgins (March 23) has called attention to rupture of the pregnant uterus resulting from previous curettage, a condition which is probably more common than would appear from the literature Curettage is commonly done by junior residents—often people holding their first gynæcological appointment—and it is important that this hazard be more widely recognised

I should like, for this reason, to report the following two cases

CASE 1 —A pregnant woman aged 37 had had seven full-term pregnancies with easy, spontaneous deliveries, and five miscarriages, the last in July, 1951 This miscarriage was apparently accompanied by considerable bleeding even after evacuation, and she was taken back to the operating-theatre, where an adherent piece of placenta was removed from the fundus with ovum forceps, with considerable difficulty

Four months later she became pregnant again, had an uneventful antenatal period, and was admitted at term in very early labour The history of the difficult evacuation was unknown at that time On examining this patient during a night round (done merely as some insurance against being called after returning home from an emergency, and not because any abnormality had been reported) I found a soft cystic swelling at the fundus of the uterus, judged to be the size of half a tennis ball, though the major part of the swelling seemed to be behind the xiphisternum The swelling was neither painful nor tender During a uterine contraction the swelling remained soft, but appeared to bulge slightly Uterine rupture was diagnosed Although the notes of the previous curettage were not at that time available, it was considered to be a likely ætiological factor



Uterus in case 1, showing large rupture at fundus Stitched incision is site of cæsarean section

The patient was in excellent condition and an immediate laparotomy was performed The placenta was being extruded through a hole, three inches in diameter, in the fundus of the uterus (see figure) There was a small amount of clot around the hole, but no free blood in the peritoneal cavity Satisfactory repair was unlikely, so a cæsarean section followed by hysterectomy was done The baby weighed 8 lb 6 oz and was vigorous from birth, and the mother had an uneventful puerperium

CASE 2 —A woman aged 37, para 3, had a normal home confinement at term in March, 1951 She was admitted to hospital two weeks later with a severe secondary postpartum hæmorrhage She looked exsanguinated and very shocked A blood transfusion was given and the uterus evacuated During the evacuation the curette was felt to pass through the fundus, and I was asked to see her Exploration of the uterus revealed a hole that would admit one finger At laparotomy there was a moderate amount of free blood in the abdomen and a small hole in the fundus of the uterus, the edges of which were bleeding There was no damage to other organs The hole was repaired with figure of eight sutures and the patient recovered uneventfully

She became pregnant again eighteen months later The antenatal course was uneventful until term, when she complained of considerable pain and tenderness in the fundus of the uterus at the site of the previous rupture There were no clinical signs of rupture other than the tenderness, but, as she was in considerable pain and very apprehensive, imminent rupture was suspected and a laparotomy was performed

The surface of the *fundus* was intact A lower segment cæsarean section was done A small area of the placenta was adherent over the site of the scar, which was slightly thinner than the rest of the fundus, but there was no evidence of impending rupture, of retroplacental hæmorrhage, or of anything else to account for her symptoms The baby was vigorous and the mother had an uneventful convalescence

The first patient, who had a large rupture, and who had not been given warning of the importance of hospital confinement following damage at curettage, was completely without symptoms Had the swelling on the fundus not been fortuitously discovered, there would have been a catastrophe In case 2 the uterus was intact, yet the patient had symptoms and a previous history which indicated laparotomy

From these cases, and the few others that have been published, it can be seen that many more cases will have to be recorded before we can assess the dangers of uterine damage resulting from curettage or draw the picture of impending and early rupture in pregnancies after such damage

ANÆSTHESIA FOR FRACTURES OF THE FEMORAL NECK

SIR,—Referring to an article on Fractures of the Femoral Neck by Dr Murray and Mr Young (March 23), Dr Rollason (May 4) writes "In my experience it is unnecessary to raise the blood-pressure preoperatively or during operation in those patients who have had chlorpromazine as part of their premedication" I am sure that Dr Rollason is absolutely right, but in my experience it is unnecessary to complicate the anæsthetic by the addition of chlorpromazine

I had a "run" of fractures of the neck of femur between Feb 25 and March 6, all in women (1) aged 87, Capener nail plate, (2) aged 86, McKee nail plate, (3) aged 78, Smith-Peterson nail, (4) aged 69, McKee nail plate, (5) aged 91, Capener nail-plate, (6) aged 85, McKee nail plate, (7) aged 86, McKee nail plate All were premedicated with morphine and atropine one and a half hours before operation and two ampoules of 'Adrenoxyl' (1 5 mg) half an hour later

Anæsthesia was induced by a sleep dose of hexobarbitone and 60 mg suxamethonium bromide, and was maintained on nitrous oxide 8 litres and oxygen 2 litres per minute endotracheally, further suxamethonium bromide being given if the patient showed any signs of reflex movement

None of these patients had any infusions or transfusions, all recovered and are alive and well except no 4, who fell forwards over her knitting on the fourth day and died of a coronary thrombosis, they were all able to take nourishment by mouth on the day of operation, and read their newspapers the next day The blood-loss during operation was minimal owing to the adrenoxyl, which reduces the bleeding time and increases the capillary resistance, and by conserving the patient's blood abolishes the need for transfusions

This appears to me to be the ideal anæsthetic for major cases, and the addition of further drugs tends only to complicate the issue Incidentally if the adrenoxyl is not given in good time it can be given immediately before operation mixed with hyaluronidase

RELATIVES IN HOSPITAL

SIR,—I was delighted to read your excellent article of May 11, which deals with an aspect of hospital medical work to which indeed scant attention is being paid

I think it can be claimed that a not unsuccessful attempt to deal with the many aspects of the problem has been made in the pædiatric sphere It is in relation to the adult patient that our failure is so grossly evident I think that you make one mistake and also that you omit to make one vital point

Firstly the mistake The wisdom and humanity needed to deal with the various anxieties and sorrows resulting from illness are not to be taught to young men at a university To attempt to do so could only encourage their seniors to continue the common and highly criticisable habit of deputing such duties to them

The omission If we are honest we will admit that for relatives in trouble there is only one man—that is, the doctor in charge of the patient, usually a consultant Any junior doctor at all is only second best Apparently, and in general, the modern hospital consultant does not think that care for relatives is part of his obligation—either to superintend or organise such care, or to take part in giving it himself in outstanding cases I think it is also very probable that regional hospital boards would hesitate before providing time for them to do such work I think, therefore, that you omit to point out the serious ethical lapse which we have allowed to grow, in treating a vital part of our obligation as an unimportant matter to be left to juniors

Until this is remedied—that is, until it is acknowledged much more generally that the care of patients' relatives is work of the highest importance requiring all the skill and experience and more, of which the best of us is capable—we may expect the press to carry complaining letters from perfectly decent people who feel that they are not being properly treated

L-NORADRENALINE THERAPY IN ACUTE RENAL FAILURE

SIR,—In his extremely practical article (May 11), Dr Mattingly has drawn attention to the value of vigorous noradrenaline therapy in hypotensive states complicated by acute renal failure He rightly emphasises with the help of a dosage chart, the need for using high concentrations of the drug, far in excess of those often recommended Therapeutic failures, when lower concentrations are used, lead to unjustifiable censure of this drug's capacity to restore the normotensive state The risk of tissue necrosis at the infusion site (to which Dr Mattingly also refers) appears to be considerably reduced by the use of local phentolamine as an antidote[1]

It would be convenient if the manufacturers would provide ampoules containing 16 mg and 32 mg of noradrenaline, for use where high concentrations are needed It would not then be necessary to open eight 4 mg ampoules and inject their separate contents into a 500 ml infusion bottle, each time a fresh one was needed In a case I reported,[2] *200 ampoules had to be opened*

Finally, in support of Dr Mattingly's experiences with acute renal failure, may I report 2 similar cases, which bore a striking resemblance to each other in *many* respects ?

Both patients were men, admitted within four days of each other, with a history of recurrent syncopal attacks and precordial pain of recent onset, in both cases the electrocardiogram on admission showed evidence of acute posterior myocardial infarction, with a pulse rate of about 46 a minute and nodal rhythm, both were shocked, with systolic blood pressures averaging 80–90 mm Hg, and in both, severe oliguria and uræmia developed

The 1st patient was completely anuric for twenty four hours after admission Noradrenaline was then started in conjunction with the régime of Bull et al[3] His output of urine gradually rose to normal over a period of a week, noradrenaline being needed the whole time to maintain his blood pressure, though in quantities not exceeding 8 mg *per* litre of infusion His blood urea reached a maximum of 262 mg per 100 ml on the fourth day after admission The 2nd patient passed only 90 ml of urine during the second twenty four period after admission, and a noradrenaline infusion was started and continued for four days (maximum strength 12 mg per litre) His urinary output reached normal about the fourth day, though his blood urea continued to rise to 198 mg per 100 ml on the fifth day after admission A further rise to 289 mg per 100 ml on the seventh day was thought to be due to melæna, which complicated his anticoagulant therapy Both patients were eventually discharged with normal renal function

CORTISONE AND IMMUNITY IN TUBERCULOSIS

SIR,—In your annotation of May 4 you state " these findings [i e , from animal experiments] also explain the lack of interference by cortisone with the efficacy of B C G vaccination In short, cortisone does not seem to impair acquired resistance in guineapigs "

Possibly, a few investigations carried out with another species—namely, the mouse—are of some relevance here This animal, by contrast with the guineapig, is virtually anergic towards tuberculin By prior vaccination with viable B C G given intravenously it can nevertheless be protected against a virulent laboratory infection, either by *Mycobacterium tuberculosis* var *hominis* systemically [1] or *M tuberculosis* var *bovis* intracorneally [2] Using the latter technique, it was found that the subcutaneous administration of cortisone acetate at the rate of 0 5 mg daily for 28 days, this period beginning with the corneal inoculation, resulted in a complete loss of that protection otherwise to be expected [3] Indeed, the corneal lesions in the cortisone-treated, vaccinated animals tended to be more severe than in unvaccinated controls

Mice are naturally endowed with some resistance towards tuberculous infections The experimental corneal disease, for instance, normally remains confined to the eye Yet, as Naguib and Robson [4] have shown, the giving of cortisone following inoculation leads to more rapid progress of the ocular lesion and, significantly, to systemic spread of the infection as well

Now that cortisone is being given much more readily to patients with tuberculous disease we must hope that, as humans, we have more in common with the guineapig in this respect and less with the mouse Otherwise, it seems, the "best-laid schemes of mice and men" will surely " gang aft a gley "

London, S E 1 **ROY GOULDING**

CÆSAREAN SECTION

SIR,—I know of a maternity hospital with slightly over 1000 annual admissions whose cæsarean section incidence in 1955 was 9 5%, nearly equal to the forceps rate, and in 1956 was 11%, slightly in excess of the forceps rate If similar situations exist in other parts of the country, and a prominent member of the Royal College of Midwives tells me that they do, then your leading article on cæsarean section (April 6) is opportune

The maternal mortality of 0 99% following cæsarean section reported by Marshall and Cox [5] for the years 1943–47, was more than 18 times as high as the maternal mortality (excluding abortions) for this country in 1955 (0 54 per 1000) It may benefit surgically minded obstetricians to reflect that if they lose only one mother in their first 183 cæsarean sections, their maternal mortality for sections will nevertheless be exactly 10 times higher than the latest published maternal mortality for the country

Professor Baird (April 27) says it is fortunate that cæsarean section is seldom indicated in young women, because it is prejudicial to further childbearing , but this seems to be a minor consideration with older women because " few primigravidæ over 30 years of age have a second child " In case others share this false belief, I offer the following information A few years ago in our practice, I questioned 1000 women regarding their pregnancies 133 did not have a child before the age of 30 Of these 133 mothers, 17 out of 32 who began to have children at thirty, had further offspring At later ages the figures were as follows

9 out of 19 who began at thirty-one
10 out of 18 who began at thirty-two
9 out of 18 who began at thirty-three
5 out of 12 who began at thirty-four
6 out of 13 who began at thirty-five
3 out of 7 who began at thirty six
2 out of 3 who began at thirty seven
2 out of 4 who began at thirty eight
2 out of 2 who began at thirty nine

2 of the women who began at thirty-six years of age had 4 children apiece Of older women, 2 who began their family at forty, 2 who began at 41, and 1 who began at 43 did not have further offspring Nevertheless, out of the total of 133 primiparæ who were 30 years or over, 65 or 48 9% did have two or more children

The forceps incidence in primiparæ rises progressively with age, but the steady deterioration of uterine function, which occurs after 25, according to Professor Baird, is essentially a primiparous condition As only 7% of secundiparæ who required forceps in their first confinement, require them again,[6] the defect in uterine function is apparently remedied by one vaginal delivery On the other hand, cæsarean section is likely to maintain this uterine dysfunction, and to ensure the need for a repeat cæsarean section in any mother over thirty, who is courageous enough to risk another pregnancy

Reading **K D SALZMANN**

CLINICAL THERMOMETERS

SIR,—Your correspondents need only look in the late Prof Samson Wright's *Applied Physiology* to find an explanation of the term " half-minute " on clinical thermometers In a footnote on p 468 he states that a half-minute is the standard time taken for the thermometer to reach equilibrium under standard conditions These not being applicable in the human body a longer period of time is necessary to reach equilibrium and accurately record the body temperature

No doubt if the thermometer were placed in blood it would reach the temperature in the requisite half-minute

London E 9 **T SUSSMAN**

SURGEON'S " PRIVILEGE "

SIR,—" A cup of tea for the doctor " was traditional long before tea-breaks became one of the greatest hindrances to industrial production in this country In cottage, council house, and castle a cup of tea was the inevitable termination of any medical rite, a privilege both to offer and receive May I add a little detail to the general terms of the letters from Mr Capener (May 4) and Miss Judge (May 11) ?

When we first heard that we had to pay, I took with me a flask of tea and a bun on those afternoons when I had long outpatient clinics Later, when a nominal charge of *1d* for a cup of tea was imposed, my wife rebelled at preparing the flask two or three times weekly I protested that " it was the principle I objected to,' but I was told that to pay *only 1d* for a cup of tea was the best bargain I should ever obtain from the National Health Service, and I had to submit

I have now a collection of receipts for *2d* upwards, including one for *6d* the account for which was sent to me by post and forwarded because I was on holiday I could not resist paying it by return of post and by postal order

At last it was realised that the book keeping was not worth the trouble, and now to satisfy the auditors a token payment of *2s 6d* a year is made for all liquid refreshments This is an even better bargain, but still ridiculous

PRIVATE PRACTICE GROUP

SIR,—Last summer a number of private practitioners, intent on preserving and extending the institution of private practice, met in London They decided to make themselves the nucleus of what they hoped would become a substantial group, and deputed to an acting executive the task of encouraging its growth

All known private practitioners in Great Britain were approached, many responded with enthusiasm and these now form, with the original nucleus, a Private Practice Group

The Group believes that on the continuance and prosperity of private practice must depend, to a great extent, the well-being of the profession and the quality of medical service rendered to the whole body of citizens, whether through private or public channels It further believes that, unless those in private practice defend its interests and speak up for it, no one else will, and doctor and citizen may one day wake to find they have lost by default one of those precious "free institutions"—that of seeking and giving medical advice and help privately, without the participation of the State

The Group's immediate aims are

1 To press for the right of private patients to receive drugs on the same terms as patients treated under the National Health Service

2 To consider again the possibility of "opting out"

3 To press for more, and less costly, private beds

4 To inquire into and, it is hoped, to promote insurance schemes to cover general medical attention

These aims are intended to supplement, but in no way to conflict with, those of the profession as a whole

It is obvious that the Group would not exist unless its members felt that private practice had become something of a Cinderella It has no wish to be or become a "splinter group," and it is approaching the organisation committee of the B M A with a view to receiving recognition

Meanwhile, the Group desires to increase its membership from among those who believe and have an interest in private practice, although, as general practitioners or consultants, they work also in the National Health Service

There is no subscription, but secretarial expenses have so far been met by donations of a half to one guinea by members

The members of the Acting Executive are L W Batten (acting president), I J Brock (acting treasurer), A E J Etheridge (acting secretary), 73, Fitzjohn's Avenue, London, N W 3, and W Russell

London, N W 3 JOHN ETHERIDGE

PREVENTION OF BEDSORES IN PATIENTS NURSED AT HOME

SIR,—As the geriatric services develop, skilled home care for the aged becomes increasingly important Bateman[1] described a new régime for the prevention of bedsores in the elderly bedridden patient in hospital he concluded that the new method was at least as effective as the old, and that much labour and time was saved I decided to instruct one district nurse in the new technique, and encourage general practitioners and the nurse to select suitable cases for a controlled trial

A letter was sent to each practitioner in the selected area, inviting his cooperation The district nurse was then requested to contact the practitioner, to find out if he agreed to the patient being included in the trial When he agreed, the procedure was as follows

A silicone barrier cream was smeared thinly and evenly on all the pressure points twice daily for a week and then once daily

The skin was washed with soap and water as infrequently as possible Once or twice a week, or when they became fouled, the pressure points were washed with warm water only, and carefully dried

The patient was urged to change his position in bed at least five times daily

As additional measures, the family doctor was asked to prescribe ascorbic acid 50 mg t d s and tolazoline 25 mg t d s The latter, besides being a cardiac stimulant, dilates peripheral blood vessels and thus improves the blood supply of the skin

23 patients were thus treated Most were elderly, and many in poor general condition, but the results were very good (in some cases broken skin healed despite poor general condition)

Result	*No*	*Remarks*
Excellent	17	Condition of pressure points satisfactory throughout trial or improved
Fair	2	Condition of skin over pressure points improved, but bedsores developed later (1 patient would not take ascorbic acid and tolazoline because of vomiting, the other refused them)
Not assessed	4	2 died and 1 admitted to hospital within a few days of starting treatment, 1 refused to coöperate
Total	23	

The number of cases treated with silicone barrier cream in this survey is small and there are no controls, but the results are very satisfactory and it is proposed to introduce this method throughout the county with the cooperation of general practitioners The treatment not only saves a great deal of unnecessary suffering in bedfast patients but also reduces the time spent on the treatment of pressure-points and obviates the labour of treating patients by the usual method of washing and rubbing with spirit The three district nurses who have had experience of the new method praise it highly They also report that elderly patients who are free of bedsores show a quick improvement in their general condition

Dr Bateman emphasised that ascorbic acid and tolazoline are an integral part of the treatment This is supported by 2 cases in our own small survey in which improvement ceased when the patient did not take the tablets

Our sincere thanks are due to the general practitioners in the Rhyl area for their ready cooperation in this trial, and to the three district nurses for carrying out the trial and recording their findings

RELEASE OF HISTAMINE IN URTICARIA PIGMENTOSA

SIR,—I was very interested in Dr Hamrin's preliminary communication (April 27) and in Dr Calnan's letter (May 11)

In studying a series of cases of urticaria I have found that, although true allergy to salicylates leading to urticaria occurs, in addition it is not uncommon to find that salicylates will affect the degree of an existing chronic urticaria This is usually seen when the patient takes acetylsalicylic acid as an analgesic, but in these cases the same effect can be obtained by giving sodium salicylate The response depends on the dose of salicylate and on the degree of urticaria at the time of administration Thus in a patient with chronic urticaria acetylsalicylic acid gr 5 may produce an exacerbation but have no effect at a later stage when the urticaria is in a milder phase Similarly, a patient showing no response to gr 5 may get an exacerbation when the dose is increased to gr 20 As suggested by Dr Hamrin and Dr Calnan, it seem possible that salicylate acts in such cases by liberating histamine

I hope to report further findings later

Bristol ROBERT P WARIN

Medicine and the Law

A Capital Murder

THE new defence of diminished responsibility under section 2 of the Homicide Act, 1957, was first raised at the trial of Shirley Campbell at Leeds Assizes last month In that case the defence succeeded, the accused being found not guilty of murder but guilty of manslaughter as required by section 2 [1]

The defence was raised again—this time unsuccessfully—at the trial at Newcastle last week of Ronald Patrick Dunbar, a labourer aged 24, on the charge of the capital murder of an 82-year-old widow and unlicensed moneylender [2] It appeared from Dunbar's own statements that he had broken into the woman's house, for the second time within a week, to rob her, and that he killed her with blows of a bottle on the head when she woke and, he thought, recognised him

Called as a witness for the defence, Dr. Robert Orton, a consultant psychiatrist, said that Dunbar was an inadequate psychopath This view was not accepted by Dr Ian Pickering, senior medical officer at Durham Prison, who was called by the prosecution. In his opinion, the accused was not a psychopath, he had an intelligence quotient of 112

In reply to cross-examination, Dr Pickering said that there were variations in the type of psychopathy but not in degree Psychopathy was an abnormality of personality which could be regarded as an abnormality of mind and could impair mental responsibility Dr Pickering agreed that, if a man were rightly said to be a psychopath, the only remaining question would be whether the abnormality of the mind would substantially impair his mental responsibility for the act in question.

Dr Pickering told the judge that he would expect a psychopath to show remorse This man had not, unless giving himself up to the police was a sign of remorse

Dealing with the effect of section 2 of the Homicide Act, the judge told the jury that it had not been put into the Act as a soft option If the case came within section 2, the jury would say so If it did not, they would not return a verdict within the section merely because the alternative was something somewhat grim

The jury returned a verdict of guilty of *capital murder*—the new term for those categories of murder still punishable by death—and Dunbar was sentenced accordingly The case may serve as a reminder that, if the section is pleaded, the onus of proof is on the defence

Death after Adder-bite

A boy of 14 collapsed and died a few minutes after he had been given serum as treatment for an adder-bite At the inquest last week,[3] a pathologist gave the cause of death as cardiorespiratory failure due to anaphylactic shock following snake bite treatment, and he added that " if the serum were not given at the earliest possible moment, it would have been nothing short of criminal neglect " The coroner, recording a verdict of death by misadventure, said that every step had been taken and it was very unfortunate that the condition arose which caused the boy's death The evidence indicated that nothing had been left undone which could have avoided the ultimate result After the boy collapsed oxygen was given and the heart was massaged After starting to beat again, the heart gradually stopped and further efforts to stimulate it were unsuccessful.

Obituary

WALTER PERCEVAL YETTS

C B E , D Lit Lond , M.R C.S.

Dr Yetts, who died on May 14 held the chair of Chinese art and archæology in the University of London and he will be remembered chiefly for his work on these subjects But his work as a doctor should not be forgotten, for he served efficiently for many years in the Royal Navy and at the Ministry of Health

He was born at Reading in 1878, the son of A M Yetts, and was educated at Bradfield College and Lausanne University He qualified in 1903 from St. Bartholomew's Hospital, and the same year entered the Royal Naval Medical Service In 1904 he was Admiralty gold medallist for naval hygiene. His visits to Chinese ports aroused his interest in Chinese art and he learned the Chinese language before he retired from the service in 1912 with the rank of staff surgeon In 1913 he was appointed acting medical officer to the British legation in Peking, and in the 1914–18 war he served in the R A M C as temporary major and deputy assistant director of medical services Embarkation After a year as deputy commissioner of medical services at the Ministry of Pensions, he was appointed, in 1920, a medical officer of the Ministry of Health, where he worked in the section dealing with sanitary administration in relation to infectious diseases

In 1927 he resigned from the Ministry to give all his time to teaching lecturing, and writing on Chinese art. His distinction in this field was recognised by his appointment in 1930 to the newly founded lectureship on Chinese art and archæology at the School of Oriental Studies in the University of London Two years later he became professor of Chinese art and archæology He occupied the chair until 1946 when he retired with the title of professor emeritus He was the first to make Chinese archæology a subject of academic study with organised courses for postgraduate degrees and diplomas

As a sinologist Yetts won many distinctions He was awarded the D LIT of London University in 1934; he was a vice-president of the Royal Asiatic Society, chairman of the China Society, corresponding member of the Vereeniging van Vrienden der Aziatische Kunst (The Hague), and honorary correspondent of the National Library of Peiping (Peking) His contributions to the literature of his subject were important His book on *Chinese Bronzes* was published in 1925, and he was also the author of six volumes in the *Eumorfopoulos Collection Catalogue* and of *Ritual Bronzes of Ancient China* (1936) His books and articles were illustrated by beautiful drawings and reproductions of inscriptions and were notable for their comprehensive bibliographies.

A S MacN writes

Yetts was a pleasant colleague, somewhat reserved in manner, and with no great liking for the restrictions of a Government office, although he performed his duties conscientiously and well His knowledge of Chinese was a great asset He was often consulted on international health work relating to China and always chosen to escort distinguished Chinese medical visitors in their tours of English hospitals and health centres But his real interest lay in Chinese art, especially in the bronzes and jade of the prehistoric period His years of retirement were spent at Chesham Bois, Bucks where he was always glad to welcome old students friends and former colleagues His chief recreation was painting in water-colours a taste which he shared with his wife, an accomplished artist

Professor Yetts married in 1912 Gwendoline Mary, daughter of the late Mr D Hughes, F.R.C S

HAROLD GUYON TRIMBLE

M D

Dr H G Trimble, associate professor of clinical medicine at Stanford University, California died on May 13 at the age of 60. He had recently been elected to the board of regents of the American College of Chest Physicians and was head of the board of examiners for its fellowship He was a member of the National Tuberculosis Association and the American Trudeau Society and he was chairman of the research committee of the California Medical Association He had come to Europe regularly since 1950 and each year had spent some time in this country attending conferences and visiting institutions and clinics for diseases of the chest. In 1954 he was awarded the Varrier Jones gold medal and he gave a lecture in London on a statistical analysis of the present-day treatment of pulmonary tuberculosis He addressed the British Tuberculosis Association in Bristol last year on pneumoperitoneum therapy

Two of his English colleagues, C W L J and M M N, write

Harold Guyon Trimble enriched the lives of all those with whom he came in contact His kindly bearing and his readiness to help were well known among his many friends all over the world and in this country in particular He was only this week to have been elected as honorary life member of the British Tuberculosis Association in addition to his vice presidency of the South East Metropolitan Tuberculosis Society The mode of his death—he was shot by a patient near his consulting room—adds to the tragedy of his passing His reputation as a physician and as a man of deep knowledge and interest in his subject had spread far from his home country, and his reputation in Europe and in the Far East was one of great scholarship and humanity

Notes and News

UNIVERSITY APARTHEID

WE have lately discussed the intention of the government of the Union of South Africa to take over the Durban medical school from Natal University [1] In a second report [2] Prof I Gordon, dean of the medical school, sets out subsequent developments

Although a technical difficulty in the Union Parliament has delayed that part of the Separate University Education Bill which deals with the separation of the Durban medical school from the University of Natal, there is no change in the intentions of the government The medical school will be dealt with in due course The Bill as first published provides for the establishment of "Bantu" and "non White" university colleges, from which the Durban medical school is in no effect distinguished In these colleges the minister of education will have the right both to limit numbers and to reject candidates for admission The minister has the power to appoint, promote, transfer, or discharge any member of the staff, this power may be exercised by any deputed officer of his department for posts designated by the minister In the interests of economy and efficiency he may discharge any member of the permanent staff The council for each college will be appointed by the governor general, the principal and the senate by the minister At the recommendation of the secretary of his department, the minister may punish misconduct by reprimand, by imposing fines up to £100, by reduction of salary and of grade, or by discharge from the service Such penalties may be applied to misconduct committed before the staff member, through this Act, became a servant of the State department Misconduct includes adverse public comment on the administration of any government or provincial department It is misconduct "to propagate any idea or take part in or identify himself with any propaganda or activity or act in a manner calculated (i) to cause or promote antagonism amongst any section of the population of the Union against any other section of the population of the Union, or (ii) to impede, obstruct, or undermine the activities of any Government department" As Professor Gordon pointed out to the minister, such a provision would place the staff at the mercy of any official who chose to interpret teaching on the social origins of disease as calculated to cause racial antagonism (For example, in the African widespread malnutrition contributes to a high incidence of cirrhosis of the liver, and the migratory labour system and poor living conditions to the prevalence of tuberculosis and syphilis, these diseases are far less common among the more fortunately placed Europeans)

In the face of this, by secret ballot 29 of the 31 full time members of the medical school staff indicated that they would resign when the Bill was enacted, while all 26 of the part time staff able to attend a meeting stated that in this event they also could not continue teaching This unrest was to some extent expressed by a deputation from the South African Medical and Dental Council to the minister The minister seemed unable to recognise any ground for anxiety or protest, and indeed he thought it the duty of the dean "to lead the staff towards a realisation of their responsibilities to the government and the country" As the medical school was heavily subsidised by the State, he thought the government was entitled to have a large say in its control He said that there was no intention of changing the status of staff, who would remain professors and lecturers There would be no reduction in salary, and he could not understand why the staff felt that they would lose prestige if they became Civil Servants Fears about the provisions for discipline were groundless—the staff would have "to deal with reasonable men who would act with justice, in all circumstances"

Despite these assurances, vigorous protest has been made not only in Durban, but by departmental heads in the Cape Town medical faculty, and by the Students Medical Council and the Medical Graduates Association of the Witwatersrand University The federal council of the South African Medical Association has expressed its grave concern Twenty six heads of departments in British medical schools wrote jointly to applaud the vigorous opposition to the threat to academic liberty and freedom of thought

---

[2] Further report on the government's intended action to remove the *faculty of medicine from the University of Natal*, with Preface by Prof I Gordon. Durban Medical School May 4, 1957

As yet there has been no shift in government policy, and the academic staff at a meeting on May 2 steadfastly resolved that they can give no assurances about retaining their posts, "because we believe that we will be unable to carry out our academic and professional work and fulfil our responsibilities to our students under the conditions which will be established for the higher education of African, Indian, and Coloured persons when the Separate University Education Bill of 1957 is enacted."

CONGRESS IN RUMANIA

From May 5 to 11 a National Congress of Medical Sciences of the Rumanian People's Republic was held at Bucharest. The invitation of delegates from all over the world gave the conference an international flavour. Twenty-seven countries were represented, and the British participants were Dr F. Dudley Hart, Dr B. H. Kirman, Dr A. MacPherson, Dr Bernard Schlesinger, Mr P. G. Shute, and Dr Denis Williams.

Prof. C. I. Parhon, the 84-year-old honorary president of the R.P.R. Academy, and formerly President of the Republic, opened the proceedings. The congress was divided into four sections devoted to physiological, rheumatic, neurological, and epidemiological problems. It soon became apparent that acute rheumatism in childhood is still prevalent in Rumania, but on the whole it is milder than the type which was so common in England in the past. Infective hepatitis is also widespread at the moment. On the other hand it seems that malaria has been virtually eradicated—an achievement which must cause considerable satisfaction to Mr Shute, whose researches in Rumania before the war played no small part in it. In the section of neurology stress was laid on conditioned reflexes and on endocrinological factors. The Bucharest Institute for Endocrinology is a pioneer in this field.

The conference was valuable in enabling medical men from all over the world to pool their ideas, but even more so in bringing them together. In commenting on it one of the British party says: "To be able to discuss China and England with a professor from Peking who had never heard of the National Health Service, to walk back to the hotel with doctors from East and West Germany and obtain an idea of their respective views and ways of life, and to compare medicine in England and Rumania with the colleagues we met—all this helped us to step over the dividing frontiers. Preconceived ideas begin to waver and a way is laid along the precipitous path towards international friendship and peace."

BRITISH EMPIRE CANCER CAMPAIGN'S RESEARCH UNIT IN RADIOBIOLOGY

In 1954 the British Empire Cancer Campaign received a donation of £25,000 to provide additional laboratories for the study of the effects of X rays and other ionising radiations on living cells, and the new laboratories were opened at the Mount Vernon Hospital, Northwood, by the Duke of Devonshire on May 20. The research unit in radiobiology which will work there is under the direction of Mr L. H. Gray, PH.D., formerly senior physicist to the Mount Vernon Hospital. The other permanent members of the team are Mr J. W. Boag, D.SC., Mr D. L. Dewey, PH.D., Alma Howard, PH.D., and Dr O. C. A. Scott. At the moment five other scientists from abroad—2 from the United States, 2 from Canada, and 1 from New Zealand—are working at the unit.

Answers to the fundamental problems concerning the action of radiation on living cells are urgently needed, and knowledge is particularly scarce about the early stages of irradiation damage which precede the changes visible under the microscope. The new unit will focus its attention on these early stages, partly because they undoubtedly hold the key to an understanding of what follows and partly because it is at the very earliest stages that there is the best chance of controlling the nature and extent of the damage caused by radiation. One method of studying early effects is to deliver all the radiation energy to the cell in the shortest possible time and to measure the chemical changes which take place in the cell or in isolated cell components at the instant of irradiation and immediately afterwards. For this purpose the unit has an electron pulse generator designed by Metropolitan Vickers, which can deliver electrons in very intense bursts. Cells exposed to the beam from the generator can be given any desired amount of radiation, up to a limit exceeding anything previously attained in a single pulse lasting only about two millionths of a second. Special methods will be used to examine the changes in the cell during and after exposure by means of flashes of light also lasting only a few millionths of a second. These studies bear closely on the use of oxygen to increase the power of X rays in the treatment of malignant disease, since oxygen is believed to augment radiation damage by participating in chemical reactions of extremely short duration.

The new laboratories have been specially designed to meet the research requirements of the unit. A single-storey section of the building includes two rooms with thick concrete walls, one housing the electron pulse generator and the other a 200,000-volt X-ray apparatus. Both machines, as well as the analytical instruments which measure the changes in the cells, are operated from a control bay between the two rooms. Another two-storey part of the building contains laboratories and offices, and a large room which serves as library, staff room, and conference room. The laboratories, which have a total floor area of 5500 sq. ft., were designed by Messrs. Waterhouse and Ripley.

GUILD OF HEALTH

A conference of 21 doctors and 28 clergy was held at Hoddesdon, from April 29 to May 2, under the auspices of the guild. A study group considered coöperation between doctors and clergy, and reached these conclusions:

Individual doctors and clergy should continue to approach each other for spontaneous coöperation over problems of their daily work.

There is a need for informal discussion-groups of all engaged in work with the sick. Means should be developed for the exchange of opinion and information between all such groups and other bodies studying similar problems.

Local church communities should so develop themselves as to provide a healthy environment which will both tend to prevent breakdowns in health and to aid the rehabilitation of the recovering sick. The importance of this kind of development in "working communities" such as schools, large factories, hospitals, and universities must be noted.

Doctors have a responsibility to participate in this process both as individual members of the community and as possessing special experience of health problems and techniques.

Coöperation of doctors with the church community can be of particular value in preparation for the critical stages of development—e.g., for marriage, childbirth, and the young family, puberty, middle age, and old age.

People in transition from one stage of development to another or from sickness to health often need to be members of small groups within the larger framework of the community, and the development of such small groups to meet particular needs is to be encouraged.

It is necessary for clergy to have a better understanding of the medical approach to healing, and for doctors to have a better understanding of the spiritual significance of healing. Plans should therefore be discussed for providing medical study courses for the clergy, and theological study courses for doctors, at teaching-school level. Whether such training should be before or after graduation or both requires consideration.

B.M.A.'s SCOTTISH HEADQUARTERS

On May 14, Dr A. H. Hall, president of the British Medical Association, officially opened the reconstructed Scottish House of the association at 6–7, Drumsheugh Gardens, Edinburgh. The reconstruction was begun in 1954. The hall has been improved and enlarged and now provides handsome accommodation for over 300 for meetings of the association's Edinburgh division and other Edinburgh medical organisations, and for Scottish B.M.A. conferences. There is now a comfortable members' common room, a dining room where members and guests can have lunches and teas, and a reading room. The common room has a bar under a club licence. The office accommodation for B.M.A. staff has been virtually doubled, and the Medical Insurance Agency now has rooms on the third floor.

Dr Hall, in declaring the building open, traced the history of the association's premises in Edinburgh from the rooms in Rutland Square, rented in 1909, to the handsome new house. He forecast that the new and enlarged premises would enable the association to discharge better than ever before its duties in furthering scientific, educational, medico-political, and social activities.

University of London

Dr P. M. Daniel, senior lecturer at the Institute of Psychiatry and honorary consultant neuropathologist at the Maudsley and Bethlem Royal Hospitals, has been appointed to the university chair of neuropathology at the Institute.

Dr Daniel studied medicine at the University of Cambridge and at Charing Cross Hospital where he held the T. H. Huxley scholarship. After qualifying in 1942 he held house appointments at Charing Cross. Soon afterwards he was appointed senior research officer in the department of pathology at the Radcliffe Infirmary and he was one of the team which made a special study of the renal circulation and described what is familiarly known as the Oxford shunt. In 1948 he was awarded the John Hunter medal of the Royal College of Surgeons of England for his share in this research and for the discovery of afferent nerves and muscle spindles in the external ocular muscles He has done experimental work on the circulation through various organs, and also on various problems in neuropathology and comparative pathology including a study of scrapie in sheep which we published last October In 1949 Dr Daniel received from the University of Oxford the degree of M A and in 1955 the degree of D M He remained at Oxford until he took up his present appointment

On April 10 the following degrees were conferred

M D—J H Evans P K Thomas

University of Oxford

Our list (May 18) of recipients of the degree of D M should have included the name of R T Turner Warwick

University of Sheffield

The title of reader in social and industrial medicine has been conferred on Dr John Pemberton, at present senior lecturer in social and industrial medicine Mr J A Griffiths has been appointed part time instructor in anæsthetics, and Dr R E Church clinical teacher in dermatology

University of Colorado

Dr J D L Reinhold, assistant to the director of the department of child health at Guy's Hospital, London, has been appointed assistant professor of pediatrics in the university from July 1

British Association of Urological Surgeons

The annual meeting of this association will be held at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2, from June 27 to 29

Beit Fellowships for Medical Research

The following elections have been made

Fourth year fellowships (£1000)

B T Donovan PH D Lond To study the hypothalamic mechanisms underlying the regulation of the onset of puberty and the mechanisms regulating the onset of œstrus, at the Institute of Psychiatry, Maudsley Hospital London

D S H W Nicol M A, M D Camb To continue his investigations of the chemistry and pharmacology of peptide fractions of insulin at the Dunn Institute of Biochemistry, University of Cambridge

Junior fellowships (£800 a year)

G A J Goodlad PH D Glasg To study the effect of the presence of a tumour on the protein metabolism of the host, at the department of biochemistry University of Glasgow

I Oswald, M A M B Camb For human electro encephalographic studies of the rôle of the emotional significance of conditioned stimuli in determining their arousal value during sleep and the mechanism of inhibition of responses to them, at the Institute of Experimental Psychology, Oxford

I C Roddie M B, B SC Belf To study the rôle of high and low pressure receptors of the vascular system in the regulation of the human circulation, at the department of physiology, Queen's University Belfast

S Varadarajan, M A Madras, PH D Camb For a comparative study of nucleotide metabolism in cancerous and normal tissue, at the department of radiotherapeutics, University of Cambridge

Pauline M Meadow, B A Oxfd PH D Lond To study the structure and mode of synthesis of bacterial cell walls, with special reference to their amino acid and amino sugar components, at the department of biochemistry, University College, London

Anglo-French Medical Bursaries

In the exchange with the Ciba Foundation, bursaries for 1937 have been awarded by the Institut National d'Hygiène to the following

Dr G A Collie Kohbabka (general practitioner Harlow) Dr F A L da Cunha (consultant obstetrician and gynæcologist Oldham and Ashton groups of hospitals), Dr R J T Gardiner (general practitioner Belfast) Dr T H Morgan (senior orthopædic registrar Nuffield Orthopædic Centre Oxford), Dr W R Probert (senior registrar thoracic surgery Sully Hospital) Dr J T Shepherd (reader in physiology Queen's University, Belfast), and Dr I McG Stewart (consultant physician Blackpool and Fylde hospitals)

More Blood-donors Wanted

On May 15, in launching a drive for over 100,000 new blood donors, Mr Dennis Vosper, the Minister of Health said that there were over 643,000 civilian donors in the National Blood Transfusion Service, but to meet developments in techniques an effective panel of 750,000 donors was needed Last year over 803,000 donations of blood were given—the largest figure ever recorded and an increase of 44,000 on 1955—and 120,000 new donors gave their blood for the first time Mr Vosper was speaking at a showing of a new film, *Blood Is Life*, which tells the story of the organisation of the service The film (two reels, running for 17 minutes) has been made by the Central Office of Information for the Ministry of Health It is intended for use in local recruitment campaigns

Anglo-French Meeting in London

A joint scientific meeting of the Royal College of Surgeons of England and the Académie de Chirurgie de Paris will be held from May 30 to June 1 at the college Papers and films will be presented by French surgeons, and the rest of the programme will be devoted to relaying by closed circuit television, in colour, surgical operations from the main theatre of St Bartholomew's Hospital to the great hall of the college This will be the first occasion in this country on which colour television has been used for a medical programme of this sort Attendance at the meetings on May 30 and 31 is by invitation, but, if seats are available, any doctor will be welcome at the meeting on Saturday, June 1, at 10 A M, when a Dupuytren's contracture will be operated on by Sir Archibald McIndoe and a cardiac operation performed under hypothermia by Sir Russell Brock Applications for seats should be sent in writing as soon as possible to the secretary of the college, Lincoln's Inn Fields, W C 2

Louis Rapkine Association

The second annual meeting of the British section of this association was held on May 6 under the chairmanship of Prof A V Hill, F R S The Abbé Breuil gave a talk on the cave paintings of Rouffignac in the Dordogne which was illustrated by slides showing some of the paintings and rock carvings of mammoths, horses, ibex, and rhinoceros found in the caves

The association was founded last year in memory of the French biochemist, Louis Rapkine Membership is open to British and French doctors and research workers in the biological sciences who have been awarded scholarships or bursaries to enable them to visit the other country Information about the association can be had from Dr G E Wolstenholme, Ciba Foundation, 41, Portland Place, London, W 1, or from Miss A M Vidal Hall, scientific office, French Embassy, 22, Wilton Crescent, S W 1

Faculty of Ophthalmologists

The following have been elected officers of this society for 1957–58

President Mr L H Savin, immediate past president, Dr John Marshall vice presidents Mr L G Mackie and Prof G I Scott hon treasurer, Mr A McKie Reid, hon secretary, Mr E F King

Islington Family Planning Clinic

A photograph of the late Dr Joan Malleson was unveiled at this clinic on May 22 Dr Malleson was one of those who helped to found the clinic in 1934, and as clinic consultant she was associated with its work until her death last year

Award for Malaria Research

At a sitting of the World Health Assembly on May 15, Dr Paul F Russell, of the Rockefeller Foundation, was awarded the Darling Foundation medal and prize for his work on the control of malaria

---

LEUKÆMIA *

RONALD BODLEY SCOTT
M A, D M Oxfd, F R C P
PHYSICIAN TO H M THE QUEEN, PHYSICIAN TO
ST BARTHOLOMEW'S HOSPITAL

CHRONIC MYELOID LEUKÆMIA

CHRONIC myeloid leukæmia is in many ways the most sharp cut of all the leukæmic syndromes It is marked by a great increase in the granular leucocytes of the peripheral blood, which are frequently to be numbered in hundreds of thousands per cubic millimetre, the least mature are scanty, and the majority fall into the grade between the myelocyte and the fully segmented neutrophil In almost every instance there is splenomegaly, often of massive proportions

Nevertheless, it is only one member, although the most common, of a group of disorders in which proliferation of myeloid cells is the characteristic feature This proliferative process may affect almost exclusively one cellular series in *myeloid leukæmia* it is the granular cells, in *polycythæmia rubra vera* it is the erythroblastic tissue, in *essential thrombocythæmia* it is the megakaryocytes In addition to these relatively "pure" proliferations an infinite gradation of intermediate forms may be distinguished, and the hyperplastic process may affect reticulin-forming cells, fibroblasts, and osteoblasts with progressive fibrosis or formation of new bone within the medullary cavity This medullary sclerosis may be the most prominent feature of the disease from its onset, and for this type the term *myelosclerosis* is reserved Its accompaniments are outstanding splenomegaly and a leuco-erythroblastic type of anæmia without significant leucocytosis In other instances medullary fibrosis accompanies the changes of chronic myeloid leukæmia (Hutt et al 1953) or supervenes on those of polycythæmia vera, of which it forms one of the recognised terminations In a third variety it is associated with a blood picture presenting the features both of polycythæmia vera and chronic myeloid leukæmia, although the totals of red and white cells seldom reach the levels attained in the "pure" forms of these disorders For this variant the term *chronic erythromyelosis* is used, and in these patients radiological evidence of intramedullary new bone formation is usually obtainable This syndrome deserves more general recognition, for it is usually accorded the diagnosis either of chronic myeloid leukæmia or of polycythæmia vera, but it is of much more indolent course than the former, and the radiological changes separate it from the latter

Besides these five clinical pictures (table VI) which stand out from among the innumerable variations of the myeloproliferative syndrome, chronic myeloid leukæmia itself may be subdivided into four types The first, or classical form, is that previously mentioned, the other three are chronic neutrophil (Weil and Sec 1932), eosinophil (Dittrich 1952), and basophil (Joachim 1906) leukæmia The last is an extreme rarity, of which I have seen no example The others are uncommon I have experience of 3 cases of the chronic neutrophil form and 2 of the eosinophil form All are marked by the presence of a great preponderance of mature segmented cells, respectively neutrophil, eosinophil, and basophil in granulation In my limited experience their course is longer than that of classical chronic myeloid leukæmia

TABLE VI—THE MYELOPROLIFERATIVE SYNDROMES

Syndrome	Cells affected			
	Granular cells	Erythroblasts	Megakaryocytes	Reticulin-forming
Chronic myeloid leukæmia	+ + +	–	+	+
Polycythæmia rubra vera	+	+ + +	+	+
Essential thrombocythæmia	–	–	+ + +	–
Primary myelosclerosis	–	–	+	+ + +
Chronic erythromyelosis	+ +	+ +	+	+ +

This lecture is concerned only with the classical variety of chronic myeloid leukæmia, and the phrase is used hereafter in this sense Exact figures for the relative frequencies of the other variants of the myeloproliferative syndrome are not available, but a rough assessment suggests that polycythæmia vera is almost as common as chronic myeloid leukæmia, while for every 100 cases of chronic myeloid leukæmia there are about 10 of chronic erythromyelosis, 15 of myelosclerosis, and 3 of idiopathic thrombocythæmia

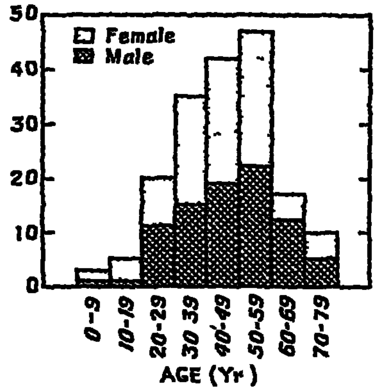

Fig 4—Age of onset of symptoms in chronic myeloid leukæmia

Incidence

The general incidence of chronic myeloid leukæmia was considered in the first lecture The insidious onset often makes it difficult to fix the date of the first symptoms, and all attempts to estimate with precision age incidence and length of survival are open to this objection In about 70% of patients the first symptoms appear between the ages of 30 and 60 In the present series the ages of onset are shown in fig 4 The mean age in males was 46 5, in females 44 6, and for the whole series of 179 patients 45 1 These figures are very similar to others published—e g, 43 6 (Shimkin et al 1951) and 44 (Ledlie 1953) There is a suggestion that the age incidence is tending to increase

In the present series females were affected slightly more frequently than males, the proportions being 52 2% and 47 8% respectively Thirty years ago males were apparently more liable to chronic myeloid leukæmia than were females A series of 116 cases collected between 1910 and 1939 was composed of 61% males and 39% females (Shimkin et al 1951) This increase in the incidence in females has been noted by other workers (Ledlie 1953)

The Clinical Picture

Initial Symptoms

The onset of symptoms in chronic myeloid leukæmia is so stealthy that few patients can recall with accuracy when they first began to feel ill Undoubtedly there is a long period, which may extend to four years, during which health is unimpaired, although the blood will show changes characteristic of the disease Occasionally chance decrees that the blood is examined during this "pre clinical" phase, and there are many reports describing the unfolding of the disease picture while the patient has been under observation (Wintrobe and Hasenbush 1939)

The commonest initial complaint is of tiredness, weakness, and disinclination for effort, it was a salient feature in nearly two thirds (58 2%) of the present series (fig 5) Next in order of frequency were the discovery of the splenic tumour by the patient (44 1%), abdominal pain (41 3%), and loss of weight (40 1%) The abdominal pain is usually referred to the left hypochondrium and often described as a sensation of weight or dragging *It is* clearly occasioned by the massive splenomegaly Less frequently

---

* The second Lettsomian lecture for 1957 delivered before the Medical Society of London on Feb 13 The first was published on May 25 and the third will appear next week

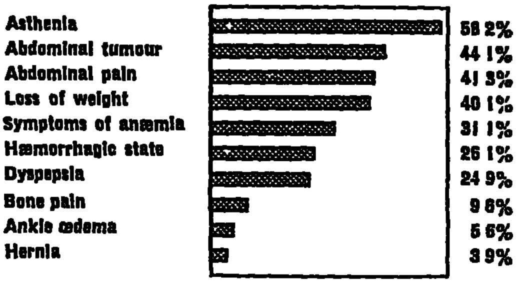

Fig 5—Presenting symptoms of chronic myeloid leukæmia in 177 patients

the first symptom is sharp pain, aggravated by respiration, and referred to the tip of the left shoulder It is presumably the result of splenic infarction with perisplenitis Loss of weight may be sufficient to cause the patient to seek advice, in several of our cases it exceeded 3 st in six months It must be related to the raised basal metabolic rate, which has long been recognised as characteristic of chronic myeloid leukæmia (Riddle and Sturgis 1927)

Somewhat less frequently than those already described, the initial complaints include such symptoms of anæmia as palpitation and dyspnœa (31 1%), digestive disturbance (24 9%), and spontaneous hæmorrhages (26 1%) The dyspepsia is usually accompanied by distension, flatulence, and loss of appetite Vomiting is uncommon, but noted in a few patients The frequency of spontaneous hæmorrhage at the onset of the disease is much higher than is generally believed At this stage the platelet-count is seldom reduced and the explanation of the hæmorrhagic state is obscure

In the third group of early symptoms are several which are interesting—though uncommon In about 1 case in 10 (9 6%) bone pain was of sufficient intensity to bring the patient to the doctor In the majority there was ill-localised aching in the bones of the legs, but in 3 it was referred to one hip-joint In 2 of these the radiological changes suggested ischæmic necrosis of the femoral head, in the 3rd an osteolytic lesion of the upper end of the bone was demonstrable Œdema of the legs was noted by a few patients (5 6%), in only 2 or 3 did this appear to be the result of thrombophlebitis, although venous thrombosis is a recognised opening symptom in the disease There was amenorrhœa in about 6% of women in whom the disease began during the reproductive period of life Priapism is well documented (Scheuer 1911) but uncommon as an initial event, it occurred in only 3 of the 86 males in this series

A final symptom, which has a practical importance, is the sudden appearance of a hernia or a uterine prolapse A hernia was the initial event of the disease in 3 9% of this series, and a uterine prolapse in 4 of 35 women over the age of 50 Common sense suggests that increase in pressure within the abdomen may precipitate such mechanical disturbances Certainly, if the occasional surgical catastrophe is to be avoided, the sudden appearance of hernia or prolapse demands careful examination of the abdomen to exclude splenomegaly

Initial Physical Signs

The physical signs of chronic myeloid leukæmia to be found at the first interview are compounded of anæmia, loss of weight, a hæmorrhagic state, and enlargement of the spleen, liver, and lymph nodes (fig 6) Pyrexia, usually intermittent, and commonly reaching 100–101°F at night, is present in about 1 patient in 3

Anæmia is variable but rarely intense Loss of flesh is the rule and in some instances profound, but all variations in habitus, from normal nutrition to emaciation, were represented in the present series A hæmorrhagic state is a presenting sign in about 1 patient in 4 It is seldom severe at this stage of the disease, and its manifestations are usually limited to spontaneous bruising, scattered petechiæ, and, more rarely, either hæmaturia or rectal bleeding A possibly related phenomenon is leukæmic retinopathy, marked by venous engorgement, with diffuse retinal œdema, hæmorrhages, and circular white exudates with surrounding hæmorrhagic halos This was noted in 11 4% of our patients when they were first seen

Enlargement of the spleen is almost constantly found at the first examination In this series it was lacking in only 2 4%, and in 72 5% the lower pole was felt below the level of the umbilicus Enlargement of the liver, on the other hand, is more variable In fully a third (34 8%) the liver was not palpably increased, and in only another third (30 9%) did its lower border extend more than 3 in beyond the costal margin

In the initial stages of chronic myeloid leukæmia significant enlargement of lymph nodes is uncommon In only a quarter (26 9%) of the present series was it judged to exist In the great majority of these there was very slight generalised lymphadenopathy In but 5 patients did it exceed this grade in 4 of them it was localised to one or two groups and moderate in degree, and in only 1 was it sufficient to occasion complaint In this patient, a woman aged 44, the presenting symptom was painful enlargement of cervical lymph-nodes, each of which measured 2–4 cm in diameter Early and significant lymphadenopathy has long been known to portend a rapid course and is to be regarded as a prognostic sign of sinister import (Weil and Isch-Wall 1930)

Less Common Clinical Features

Chronic myeloid leukæmia differs from other forms of leukæmia in its tendency to run a uniform course with symptoms which are familiar and relatively few Some less common features, however, are observed from time to time

Apart from purpura, cutaneous lesions are uncommon In only 2 of the present series did the skin present specific infiltrations, and in both these consisted of grey blue cutaneous and subcutaneous nodules widely scattered over the chest and abdomen Such lesions have been described occasionally by other authors (Paul and Limarzi 1942), they are generally considered to be of evil portent, and the truth of this belief was supported by both the present cases Herpes zoster is not rare (Wile and Holman 1940) and was noted in 7 of this series In 2 it was generalised

Skeletal infiltrations are usually regarded as uncommon in chronic myeloid leukæmia (Silverman 1948), but they were noted in 12 (6 7%) of the present series—3 of which have already been mentioned In 4 there was subperiosteal infiltration with some destruction of bone at the upper extremity of the femur or humerus, in 1 there were multiple chloromata of the skull, and in 1 similar tumours,

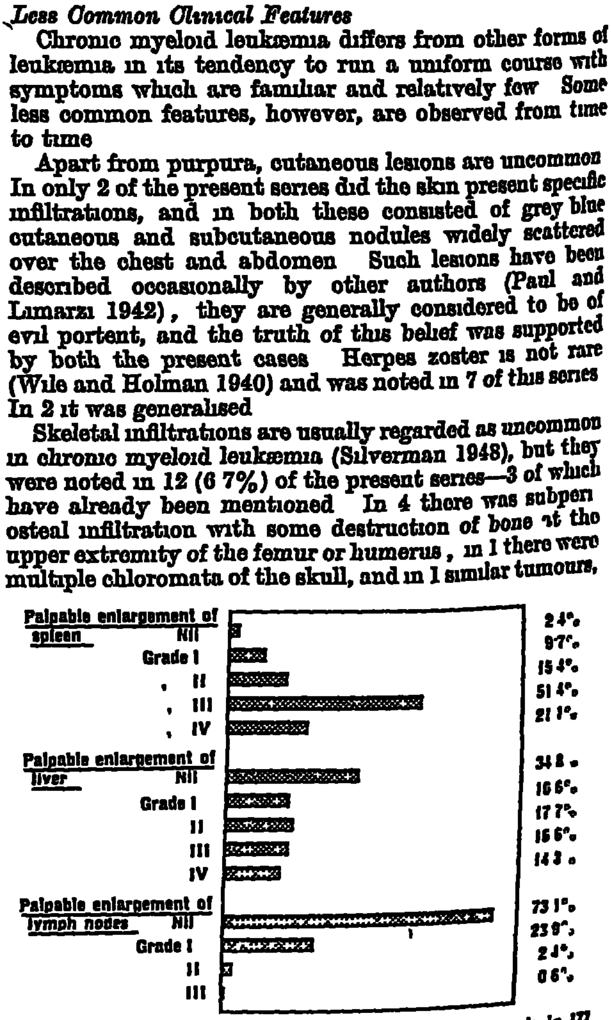

Fig 6—Presenting physical signs of chronic myeloid leukæmia in 177 patients

but lacking the green colour, were found on the ribs 1 patient had extensive osteolytic lesions of the upper ends of the humeri. In 2 patients solitary bone tumours were found—in one (who sustained a pathological fracture) at the lower end of the femur and in the other at the upper end of the tibia This variety is rare, and only 3 examples have been recorded in recent years (Townsend 1939, Minimi and Scardigli 1951, Nesbitt and Roth 1955) Swelling of, and effusion into, the knee-joints was observed in 1 patient and similar affection of the wrists in 1 other These articular lesions have been shown to depend on leukæmic infiltration of the synovial membrane (Bedwell and Dawson 1954)

Symptoms due to infiltration of the cardiovascular apparatus are exceptional, but pericarditis has been reported (Bierman et al 1952) In 1 of the present series pericardial effusion was a presenting feature, it disappeared after irradiation of the spleen, and the patient survived nearly three years in good health Pericardial effusion was noted also during the course of the illness in 1 patient with chronic neutrophil leukæmia

The frequency of dyspepsia has already received comment, but a neglected, although not uncommon, symptom is diarrhœa, which disappears with treatment of the leukæmia 3 patients in the present series developed massive ascites in 2 it followed infarction of the spleen, and in the 3rd, in whom its onset was accompanied by hæmatemesis, the cause was thrombosis of the portal vein

Associated Diseases

Associated diseases were infrequent in this series It has been suggested that peptic ulceration is common in chronic myeloid leukæmia (Wintrobe 1956), but here it was noted in only 7 patients Urinary calculus might well be expected, but it occurred in only 3, and gout in only 1 Apart from terminal pneumonia, intercurrent infection is strangely uncommon, but pulmonary tuberculosis was found in 6 of this series, in 1 of whom it assumed the miliary form This patient is of interest in that the miliary shadows disappeared under treatment with streptomycin, the leukæmia was controlled with busulphan ('Myleran'), and she lived for three and a half years after the double diagnosis was established In 1 patient tuberculous peritonitis complicated the disease

Pregnancy

6 of the 52 women in the childbearing period of life became pregnant during the course of the disease, 1 on two occasions All were delivered normally at full term, there was no maternal, and only one neonatal, death There was no evidence that the disease was made worse, and it is not an obligatory reason for termination of pregnancy (Allan 1954)

Blood Picture

As in all forms of leukæmia, diagnosis depends on examination of the blood, which, in the chronic myeloid variety is almost always characteristic and conclusive There is usually some anæmia, although in 10% of the present series the hæmoglobin level was above 80% on the first examination, in nearly half it lay between 40% and 60% The leucocyte-count is greatly increased, being between 100,000 and 300,000 per c mm in half the patients In 3 instances it exceeded 1,000,000 per c mm (fig 7) The increase is entirely due to an excess of cells of the granular series, from the neutrophil myelocyte to the fully segmented neutrophil Moderate increases in eosinophil and basophil cells are common, but myeloblasts and promyelocytes are scanty At this stage the platelet count is usually raised, sometimes above 1,000,000 per c mm Occasional normoblasts are often seen in the film

Treatment

The ease with which therapeutic remission may be obtained in chronic myeloid leukæmia separates it from other forms of leukæmia This characteristic does not appear to depend on an inherent tendency to spontaneous remission, for the usual course of the illness before the institution of treatment is one of steady decline In untreated cases phases of transient amelioration occur in only 6% (Minot et al 1924)

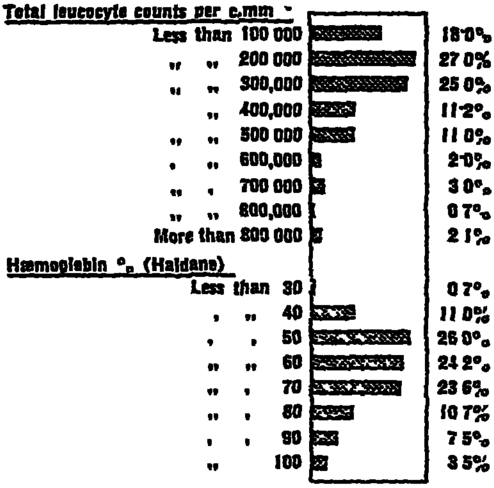

Fig 7—Initial blood-counts of 144 patients with chronic myeloid leukæmia

The first agent shown to have therapeutic effect was arsenic, in the form of Fowler's solution, and its use by Lissauer (1865) was the pioneer venture in the chemotherapy of malignant disease It held the field until displaced by the röntgen ray, applied first by Pusey (1902) in the United States and three years later in this country by Ledingham and McKerron (1905) Similar results were obtained with benzol (Korányi 1912), radium (Rénon et al 1913), mesothorium, and thorium X (Zadek 1933)

There was little further advance until about ten years ago, and in this past decade nitrogen mustard (Karnofsky 1948, Gardikas and Wilkinson 1951), urethane (Paterson et al 1946), radioactive phosphorus (Lawrence et al 1948), desacetylmethylcolchicine (demecolcine, 'Colcemid') (Moeschlin et al 1953), and 1–4 dimethanesulphonyloxybutane (busulphan, myleran) (Galton 1953a) have been introduced

It is impossible to review the use of all these agents, indeed many are now largely of historical interest only The three which require serious consideration are radiotherapy, demecolcine, and busulphan Of the remainder, radium and its relatives, nitrogen mustard, and urethane have no longer a place in the treatment of chronic myeloid leukæmia, and radioactive phosphorus has no advantage over conventional radiotherapy

Radiotherapy

Deep X ray therapy has been the mainstay of treatment in chronic myeloid leukæmia for fifty years Its advantages and drawbacks are well known In this series the great majority of patients have been treated by irradiation of the spleen The initial dose was usually 50r, and the total, depending on the rate of fall in the leucocyte-count, lay between 400r and 1200r, spread over one to three weeks Treatment has been stopped when the count has reached 15,000–20,000 per c mm, after which there follows a gradual drop to 8000–10,000 per c mm over the next three weeks Severe leucopenia has been observed only on three or four occasions The usual effects have been shrinkage of the spleen, disappearance of all general symptoms, and a return to apparently normal health Further courses of treatment have been dictated partly by recurrence of symptoms and partly by a rising white cell count In the absence of symptoms it has not usually been thought necessary to irradiate until the count exceeded 75,000 per c mm

The immediate results were excellent Remissions varied greatly in duration, from three months to as long, in 1 instance, as five years The mean is about nine months Second remissions are shorter and, as the disease progresses, they become less complete Eventually a state may be reached where there is massive splenomegaly and persistent anæmia but a leucocyte count of 20,000 per c mm or less forbids further irradiation More often the moment comes when the malignant process quickens its tempo the predominating cell becomes less and less mature until the blood is flooded with myeloblasts, the platelet count falls, and profound anæmia develops This myeloblastic crisis is the common termination of the disease

The place of radiotherapy in the treatment of chronic myeloid leukæmia is so well established that detailed discussion would be out of place Its disadvantages are the necessity for expensive apparatus and the inevitable succession of remission and relapse which this particular form of therapy imposes No attempts to make smooth the undulant pattern of this course have been fully successful

Demecolcine

Demecolcine (colcemid), an alkaloid isolated from extracts of *Colchicum autumnale* (Reichstein and Santavy 1953), was first shown to be effective in chronic myeloid leukæmia by Moeschlin et al (1953) In the present series it has been used in only 6 patients The practice was to begin treatment with an oral dose of 3 mg daily, this was cautiously increased to 5 mg after three or four days and, in some cases, to 7 mg or even 10 mg later

The fall in the leucocyte count may be precipitous and, if treatment is interrupted for more than three or four days, it may rise as rapidly as it fell, and further response be difficult to obtain

Side effects were common and included alopecia and generalised erythema Shrinkage of the spleen was slow and incomplete, the differential leucocyte count seldom returned to normal, and anæmia responded slowly

There is *no doubt that chronic myeloid leukæmia can* be adequately controlled with demecolcine (Leonard and Wilkinson 1955), but our experience did not encourage us to persevere with it Other workers have encountered even more severe reactions and have reached similar conclusions (Bousser and Christol 1955)

Busulphan

Busulphan (myleran) is a product of the Chester-Beatty Research Institute (Haddow and Timmis 1953) It was rapidly shown to have a virtually specific action on myeloid cells in laboratory animals and to be effective in the treatment of chronic myeloid leukæmia in man Reports testifying to its value have come from many countries (Consoli and Napoli 1955, Galton and Till 1955, Haut et al 1955, Pribilla and Stollberg 1955, Soares and Valente 1955, Blackburn et al 1956, Louis et al 1956, Schilling and Meyer 1956) It is now the routine method of treating this disease in my clinic and has been used in the last 23 patients

Treatment does not necessitate admission to hospital, the initial daily oral dose is 0 06 mg per kg body weight, usually equivalent to 4 mg Blood counts are made at first at intervals of a fortnight The leucocyte count falls slowly over four to six weeks and is followed by a rise in the hæmoglobin level and by shrinkage of the spleen A return to normal health is achieved in two or three months The dose is adjusted to that sufficient to maintain a leucocyte count of about 10,000 per c mm and a normal platelet count, and maintenance treatment is continued at this level (fig 8) Complete remission was obtained in all but 2 of our patients, and they had already become resistant to irradiation There are several in this series who have been maintained in complete remission for over fifteen months

It has been suggested that myeloblastic relapse may occur earlier in patients treated with busulphan than in those irradiated (Blackburn et al 1956) There is no solid support for this contention, indeed, the extreme variations in the course of the disease would make it difficult to obtain statistical proof At present busulphan is undoubtedly the most convenient means of treating chronic myeloid leukæmia It has the advantage, not possessed by radiotherapy, of maintaining remission until the disease is brought to a close by a final myeloblastic explosion and, so far as is known, its results compare favourably with those obtained by other methods

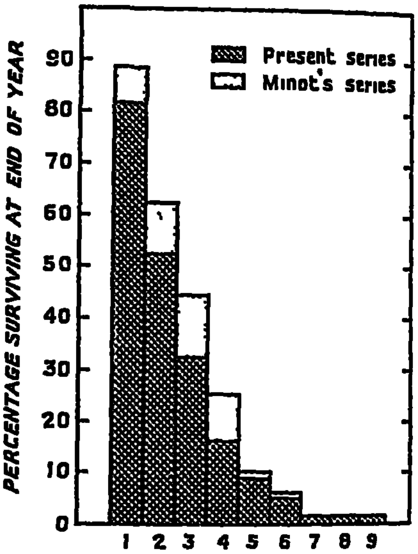

Fig 8—Survival of patients with chronic myeloid leukæmia 124 patients in present series compared with untreated series collected by Minot et al (1924)

When myeloblastic relapse takes place, busulphan is useless, and irradiation both ineffectual and dangerous The therapeutic problem becomes that of acute myeloblastic leukæmia, and the only drug of any value is 6 mercaptopurine In this series, it must be confessed, the results have been unsatisfactory *The leucocyte count* has always been reduced, but there has been little change in the appearance of the bone marrow, and no true remission has been obtained, although some clinical improvement has been evident In several patients the speed of the decline appears to have been slowed 6 Mercaptopurine will also control the disease satisfactorily in the early stage before myeloblastic relapse has occurred (Burchenal et al 1953)

Subsidiary Treatment

This discussion has concerned itself so far only with what might be called "specific" measures for controlling the leukæmic process The various subsidiary *forms of* treatment do not require detailed consideration

Blood transfusion is seldom needed until acute myeloblastic relapse has occurred, when it must be used to preserve a safe level of hæmoglobin while attempts are made to procure remission with 6 *mercaptopurine*

Splenectomy —Mention has already been made of the patient with severe anæmia, massive splenomegaly, and a leucocyte count too low for either irradiation or chemotherapy to be safe It seems probable that the anæmia in this situation is in part hæmolytic in origin (Galton 1953b), although clear cut evidence of excessive destruction of blood was not obtained in our patients

In 2 of this series, who reached this position of impasse, splenectomy was undertaken in one myeloblastic relapse took place three months later, the other enjoyed a complete remission for nine months before the final acute phase supervened This was marked, as observed by other workers in like circumstances (Laignel Lavastine A et al 1932), by striking enlargement of lymph nodes A 3rd patient, aged 8 years, underwent splenectomy at another hospital a year after the onset of the disease He Operation was preceded and followed by irradiation died ten years after his initial symptoms, and nine years after his splenectomy, from pulmonary infarction

Splenectomy in chronic myeloid leukæmia was first undertaken by Bryant (1866) of Guy's Hospital Both his patients died, and he concluded that the operation was theoretically unsound No-one would challenge this opinion of splenectomy as a definitive treatment, but occasionally circumstances may arise in which it will provide the patient with several more months of useful existence (Puorger and Aymon 1948)

Prognosis

Chronic myeloid leukæmia remains a fatal disease, but the duration of life from the first symptom shows remarkable variation In the great majority of cases myeloblastic transformation rings down the final curtain Only 39 of this series were examined post mortem, and in 23 this anaplastic change was the only cause of death discovered Bronchopneumonia was responsible for 4 deaths, tuberculosis for 4, pyelonephritis for 2, pulmonary embolism for 2, chronic cor pulmonale for 2, and coronary thrombosis and staphylococcal septicæmia for 1 each The relative rarity of terminal infection is noteworthy and contrasts strongly with its frequency in other forms of leukæmia

✓ It is impossible to foretell when myeloblastic relapse will occur, but its appearance always foreshadows the end In some patients this change has supervened only five months after the initial symptom, in others the interval has been as long as seven years In the present series the mean survival in 160 patients who have died was 32 4 months The variability is sufficient to deprive a mean figure of much value This length of survival does not compare favourably with those of other series, a selection of which in terms of months are 36 (Ledlie 1953), 37, 36, and 38 (Shimkin et al 1951), 42 (Krebs and Bichel 1947), 38 (Leavell 1938), 40 (Hoffman and Craver 1931), and 41 (Minot et al 1924) It is possible to explain some of this difference by the action of selection, the variation in the course of the disease, and the difficulty in dating its first symptom with precision It is safe, as a generalisation, to say that the mean survival from the first symptom in chronic myeloid leukæmia is about three years

There is little evidence that treatment prolongs the life of patients with this disease Fig 8 shows the proportion surviving at the end of each year, compared with a series of patients who received no irradiation, collected by Minot et al (1924) The two curves are almost identical, and the conclusion must be drawn that, as regards survival in this disease, there has been no improvement in the outlook during the past thirty three years

In any patient it is virtually impossible to foretell the course that chronic myeloid leukæmia will take In this series the survival is somewhat longer in females, with a mean of 35 2 months, than in males, for whom it is 29 5 months The disease lasted longer in the younger patients (table VII) It is perhaps justifiable to conclude that the prospects of long survival are better in young women than in old men

The outlook, moreover, bears no relation to the total white cell count when the patient is first seen, although the presence of a high proportion of myeloblasts naturally indicates the impending onset of acute relapse There is no difference between the duration of those who present with a hæmoglobin level below 9 g per 100 ml and of those with a lesser degree of anæmia Fever is usually, but not necessarily, an unfavourable sign, if it vanishes when the leukæmia is treated it is robbed of any evil significance The suspicion that survival is shorter in those whose spleens are of great size when first seen cannot be supported statistically, but the impression remains Outstanding enlargement of lymph-nodes in the early stages indicates a short course, and the specific skin lesions portend rapid deterioration Skeletal lesions are usually seen only in the later stages, but in the rare instances in which they are responsible for the presenting symptoms the progress of the disease is not necessarily rapid

TABLE VII—SURVIVAL FROM ONSET OF SYMPTOMS OF CHRONIC MYELOID LEUKÆMIA

—	No of patients	Mean survival (mos)
Total	160	32 4
Males	76	29 5
Females	84	35 2
Age at onset (yr)		
< 30	23	39 0
30–59	109	31 0
60–79	28	24 0
Date of treatment		
Before 1939	90	35 0
After 1939	70	30 0

Conclusion

It is impossible to contemplate chronic myeloid leukæmia with any feelings of satisfaction It is true that many new therapeutic agents have been devised, but its victims live no longer now than when our grandfathers treated them with Fowler's solution We may perhaps be justified in claiming that our methods preserve the patient's well-being and permit him to lead an active happy life for the greater part of his illness, although we are still unable to predict with any accuracy how long it will take to run its course

DEATHS ASSOCIATED WITH STEROID-HORMONE THERAPY

AN ANALYSIS OF 18 CASES

K D Allanby
M D Lond , M R C P
ASSISTANT TO THE DIRECTOR OF THE DEPARTMENT OF MEDICINE, GUY'S HOSPITAL MEDICAL SCHOOL, LONDON

Most of the side effects and complications resulting from the use of cortisone and corticotrophin are not dangerous and cease when the hormone is stopped, but some complications have been serious and some fatal The fatal complications include infections, particularly "silent" pneumonia, which may cause rapid death (Page 1954, Jacobs and Clifford Rose 1955), septicæmia (Shaper and Dyson 1955), aplastic anæmia (Snively et al 1953), perforation of the ileum in regional ileitis (Sauer et al 1953), perforation of the colon in ulcerative colitis (Tulin et al 1952), massive gastro intestinal hæmorrhage (Gray et al. 1951, Sauer et al 1953), and hypersensitivity to corticotrophin (Hill and Swinburn 1954) Deaths have also been reported during the treatment of bronchial asthma (Savidge and Brockbank 1954), scleroderma (Lunseth et al 1951, Sharnoff et al 1951), and rheumatoid arthritis (Finck 1955) In addition, Salassa et al (1953) and Lewis et al (1953) have attributed deaths shortly after operation in patients previously receiving cortisone to adrenal insufficiency under conditions of stress

The published reports give the impression that cortisone and corticotrophin may have been unjustly blamed for some deaths, and this is likely to be the case when the disease under treatment is itself potentially fatal, and liable to similar complications during its natural history (for instance, perforation and hæmorrhage in ulcerative colitis) In view of this, details have been collected of all deaths during treatment with cortisone or corticotrophin at Guy's Hospital, in an attempt to decide whether the treatment was responsible, how death occurred, and whether it might have been prevented From 1949 until December, 1955, all patients receiving steroids at Guy's Hospital were under the supervision of the Department of Medicine, and during these years more than 400 patients received either one or both hormones Some of these cases were recorded by McGehee and MacLean (1954) Since December, 1955, when cortisone became available on prescription, many other patients have received treatment but the exact number is not known Dosage schemes have varied from short courses of corticotrophin by daily intravenous drip to maintenance therapy with oral cortisone, sometimes for as long as four years continuously The histories of 18 patients who died during treatment are available, but since some died at home or in other hospitals, accounts of their final illnesses are not always complete A necropsy was not possible in every case No death during substitution therapy for Addison's disease or hypopituitarism, or following adrenalectomy or hypophysectomy for carcinomatosis has been included

The accompanying table shows the cause of death—i e , fatal complication and details of steroid therapy in each of the 18 patients Steroid therapy was considered directly responsible for 9 deaths and probably for 2 more It cannot be blamed for 2 of the deaths, and it is unlikely to have been the cause of a further 2 In the remaining 3, the part played by cortisone or corticotrophin is more debatable

The Rôle of Infection

Infection caused most deaths in this series—at least 6 (and probably 7) out of 18

Man and laboratory animals are remarkably susceptible to infection whilst under the influence of cortisone or corticotrophin (Glaser et al 1951, Germuth et al 1952, Glaser and Loeb 1952, Mogabgab and Thomas 1952) This susceptibility has long been recognised in naturally occurring Cushing's syndrome (Cushing 1932), and in the 189 cases reviewed by Plotz et al (1952) death was due to infection in nearly half of the 114 in which a necropsy was performed

Thomas (1953) has pointed out that cortisone potentiates and enhances all known infections, and in mice and rats ordinarily non pathogenic organisms may be rendered pathogenic (Gledhill and Rees 1952, Le Maistre and Tompsett 1952) Thomas believes that cortisone acts directly on the cells of the reticuloendothelial system, since blockade of this system in animals, by injecting saccharated iron or thorotrast, produces effects identical with those of cortisone—namely, failure to clear injected cocci from the blood, dissemination of organisms that usually produce only local infections, and accelerated absorption of meningococcal toxin injected intradermally. There seems to be no evidence that cortisone either stimulates the growth of bacteria or increases their virulence in vitro The increased susceptibility and mortality result from depression of the host's defence mechanisms

Jawetz (1954) found that doses of antibiotics just sufficient to control infections in normal animals failed to protect animals receiving cortisone, but the infection could be overcome by increasing the dose, and bactericidal antibiotics were far more efficient than bacteriostatic ones, which had to be given in far larger amounts Jawetz explained this difference on the grounds that a purely bacteriostatic antibiotic will succeed only when the host's defence mechanisms are intact, and he believes that cortisone seriously interferes with those mechanisms It is doubtful whether Jawetz's work has any clinical application in the choice of antibiotics for, as he himself pointed out, the doses used clinically are far in excess of those actually needed in most ordinary infections

SUPPRESSION OF SIGNS OF INFECTION

One of the most disquieting features of many of the recorded deaths during steroid therapy is the suppression or masking of the symptoms and signs of infection Patients may appear well despite active infection, and Kass et al (1950) showed that blood and sputum cultures remained positive in patients with lobar pneumonia who were given corticotrophin, although fever subsided and great clinical improvement occurred This masking effect delays diagnosis and treatment, so that a sudden and often fatal collapse may be the first indication of infection

In the Guy's series, 2 patients collapsed suddenly, although the presence of a complicating infection was realised

Case 1—A woman, aged 23, had scleroderma, and cortisone was given in short courses (100 mg daily) during 1953 In 1954 she received cortisone (100 mg daily) almost continuously from June until August, when she was discharged to continue the same dose at home She had gained 20 lb She died in November and, according to her doctor, cortisone was stopped about ten days before her final illness She had a cold and mild bronchitis, and her doctor said she was "twice her normal size" As her condition was mild he did not visit again until called a week later, when he found some tachycardia but no pyrexia There were moist sounds at the left base and he diagnosed bronchopneumonia antibiotics were prescribed He was astonished to hear of her death twelve hours later, since he had certainly not considered her ill enough to warrant removal to hospital Necropsy was not obtained

Case 2—A man, aged 59, received cortisone (125 mg daily by mouth) for severe rheumatoid arthritis, but it had to be stopped after seven days owing to retrosternal pain Cardiac infarction was diagnosed, and confirmed by E C G Three weeks later, cortisone was restarted (100 mg daily) and his arthritis was much improved though he was troubled by slight bronchitis Ten weeks later a cough and sputum developed, and his temperature rose to 101°F A chest radiograph showed a wedge shaped opacity in the left lung Cortisone was stopped and penicillin and streptomycin started Twenty four hours later he collapsed and his blood-pressure was unrecordable , despite treatment by noradrenaline drip, he died five hours later At necropsy the left lower lobe was in the stage of red hepatisation There was a healed cardiac infarct The adrenals were macroscopically normal

ADRENAL FAILURE AS A CAUSE OF DEATH

This sudden collapse during steroid therapy has often been described, usually in association with acute infection (Page 1954, Jacobs and Clifford Rose 1955, Shaper and Dyson 1955) It was encountered in 3 cases in the present series (cases 1, 2, and 3) , and case 7 probably died in the same way

A similar collapse, postoperatively, has been reported by Salassa et al (1953) and Lewis et al (1953), and case 8 is probably an example

Case 8 —A woman, aged 67, developed intractable headache, and temporal arteritis was diagnosed She was known to have had attacks of diverticulitis, but after careful consideration, and because her symptoms were intolerable, prednisolone (20 mg daily) was started, with almost immediate relief Four weeks later perforation occurred and prednisolone was promptly stopped Four days later laparotomy confirmed a small perforation through an area of diverticulitis Twenty hours after operation she suddenly collapsed and, despite temporary improvement with intravenous hydrocortisone, death soon followed At necropsy there was no evidence of generalised infection and the peritoneum was quite clean

An almost identical sequence of events may occur in Addison's disease as a result of infection, trauma, operation, or other stress, and cortisone will protect a patient in such circumstances It might seem difficult to believe that a patient receiving large doses of cortisone and perhaps showing many of the signs of Cushing's syndrome can in fact be potentially adrenal deficient, but Thorn et al (1953) pointed out that this indeed can be the case, and that such a patient does not respond normally to stress A normal adrenal response to intravenous corticotrophin does not occur in a patient who has received cortisone for twenty days until the fourth day after its cessation (Renold et al 1952), and furthermore Calkins et al (1955) concluded that, in patients who had had cortisone for long periods, corticotrophin secretion was impaired for a similar time after withdrawal Nabarro et al (1955) warned that prednisone prevented the normal adrenal response to infection, and Ward et al (1953) stated that the normal adrenal response to stress was inhibited for days or months after hormone therapy They recommended large supplementary doses for patients undergoing surgery or when a severe infection developed, mentioning particularly the need for bigger doses after a perforation (see case 8) Salassa et al (1953) reported 2 deaths within twenty four hours of operation in patients who had had cortisone, and both deaths were attributed to adrenal failure The only abnormal post-mortem finding was atrophy of both adrenals Salassa et al examined the adrenals at necropsy in 42 patients who had had cortisone and found significant atrophy, particularly in patients receiving cortisone up to the time of death They believe severe stress may cause adrenal failure for as long as eighteen months after cortisone withdrawal, and recommend consideration of supplementary cortisone for all patients undergoing surgery in such circumstances

It is often difficult to be certain, in reported cases, whether hormone therapy was stopped, when infection or other stress occurred, and whether significant adrenal atrophy was found at necropsy In the 3 patients who collapsed as a result of infection in this series, cortisone had been stopped one week previously in case 1, twenty-four hours before the sudden deterioration in case 2, and on the day before death in case 3 In a case reported by Jacobs and Clifford Rose (1955) the daily dose of corticotrophin was increased from 80 mg to 120 mg when the patient was admitted collapsed and comatose with pneumonia Penicillin was also given, with dramatic improvement, only for relapse and death to follow two days after the withdrawal of corticotrophin, fifteen days after the initial collapse

Unfortunately the adrenals were not fully examined in every case in the Guy's series In case 2 the glands were not considered abnormal, and in case 3 they were reported as macroscopically normal In case 8 (a post-operative death) the glands were small (rt 6 5 g , lt 4 7 g), but no convincing microscopic changes were found Shaper and Dyson (1955) made no mention of the state of the adrenals in their 2 cases, but in Page's (1954) cases they were regarded as normal Jacobs and Clifford Rose (1955) considered that the adrenals of their patient who died after stopping corticotrophin were in a resting phase, and found severe atrophy and hæmorrhage in those of another who had had cortisone Evidence published in this country about adrenal atrophy in patients who have died suddenly is scanty and inconclusive, but reference has already been made to the work of Salassa et al (1953) in the United States

PREVENTION OF ADRENAL FAILURE

Surgeons are often reluctant to continue hormone therapy when operation becomes necessary, usually on the grounds of delayed wound-healing , but this risk has probably been overestimated, and, moreover, it seems unlikely to be much reduced by stopping cortisone only a day or two before operation Equally, physicians may feel bound to stop steroid treatment should infection occur Sudden withdrawal of cortisone, however, leaves the patient without endogenous corticotrophin, and though adrenal failure is not inevitable, the logical course is to continue cortisone or corticotrophin, often in much bigger doses, until the risk is past (Salassa et al 1953, Thorn et al 1953, Ward et al 1953, and Jacobs and Clifford Rose 1955) It may be necessary to increase the dose very considerably for a short time, perhaps to the equivalent of cortisone 300 or 400 mg daily, and whilst cortisone may be given intramuscularly to provide a depot, at least half the dose should be given orally in the early stages to ensure rapid absorption and action There is no reason to believe that adrenal failure is less likely in patients receiving corticotrophin, for, as Salassa et al (1953) have pointed out, it similarly depresses endogenous corticotrophin production It might seem logical to give corticotrophin to stimulate normal adrenal function when added stress threatens patients receiving cortisone, but it takes at least four days to get an effective response to corticotrophin in such patients Thus, patients receiving steroid therapy require increased doses of the appropriate hormone during periods of stress , and the need for large doses of antibiotics as soon as any infection is suspected cannot be overemphasised

Deaths Following Perforation

In 3 patients death followed intestinal perforation (see table) Perforation of the colon complicated ulcerative colitis in case 10 and diverticulitis in case 8 , and in case 9 perforation involved the terminal ileum affected by polyarteritis nodosa Though perforation usually occurs through a pre existing lesion in the gastro-intestinal tract, steroid hormones can produce peptic ulceration in previously normal persons , and though the exclusion of patients with an ulcer history from steroid therapy will diminish the chances of perforation, the risk remains

All 3 patients already had a gastro intestinal lesion Case 8 has already been discussed the presence of diverticulitis was known and steroid therapy was only started after careful consideration, but death was clearly the result of it

Case 9 —A woman, aged 57, received two courses of sulphonamide for tonsillitis Soon afterwards she became acutely ill with vomiting, diarrhœa, and purpura, and melæna followed Corticotrophin (40 mg daily) was started, and on the tenth day generalised abdominal pain and distension began This was attributed to a retroperitoneal hæmorrhage, and was treated with gastric suction and intravenous fluids On the fourteenth day corticotrophin was stopped and cortisone 200 mg substituted 100 mg was given on the next day During this time oxytetracycline was given intravenously, but she died on the sixteenth day At necropsy a perforation (1 5 × 0 5 cm) was found 30 cm from the ileocæcal valve The microscopic changes of polyarteritis were seen in the vessels at the edges of the perforation and in a large Peyer's patch which had ulcerated

The steroid's anti inflammatory action seems the likely cause of perforation, but it is hard to say that the ileum might not have perforated irrespective of therapy A third possibility is that cortisone or corticotrophin may produce areas of visceral infarction by causing intimal fibrosis and obliteration of the vessels in polyarteritic lesions Shick et al (1950) described such infarcts in the organs of 2 patients dying from polyarteritis, and Sharnoff et al (1951) reported similar changes in a patient who received cortisone for scleroderma Diffuse fibrinoid necrosis of the arterioles in a patient who died from jaundice and anuria whilst receiving corticotrophin for scleroderma was found by Lunseth et al (1951), and they thought this might be a change in immunological response induced by the hormone, though there seems little evidence for this The lesions at the edges of the perforation in case 9 have been carefully re examined but there is nothing to suggest diffuse fibrinoid necrosis It is considered that an already ulcerated and necrotic area of ileum perforated, and that cortisone hastened this, though it might have occurred in any case Presumably steroid therapy carries this risk of perforation in polyarteritis nodosa with intestinal lesions, but it would be unreasonable not to accept this risk in treating a disease so often fatal

IN ULCERATIVE COLITIS

Steroid therapy has never been regarded as a cure for ulcerative colitis, but remissions may be produced in a high proportion of patients, though relapse often follows withdrawal (Elliott et al 1951, Halstead et al 1951, Truelove and Witts 1955) Unfortunately perforation has been reported as a complication (Halstead et al 1951, Kirsner and Palmer 1951, Gray et al 1952, Tulin et al 1952)

Case 10 —A man, aged 75, had had diarrhœa (6 or 7 stools a day) for three weeks His condition rapidly deteriorated and, on admission, the motions contained blood and mucus Hb 70% Sigmoidoscopy showed an acutely inflamed hæmorrhagic mucosa Ulcerative colitis was diagnosed, and despite blood transfusion and antibiotics he grew steadily worse Corticotrophin was started by intravenous drip, the dose varying between 20 and 60 mg daily He improved strikingly, but after eleven days abdominal distension developed and a perforation was suspected He died on the twelfth day after a total of 420 mg Necropsy showed peritonitis, and a fresh perforation was found in the transverse colon The colon showed acute ulcerative colitis, with a little healing and fibrosis

Most of the reported perforations were in uncontrolled series, but in Truelove and Witts's (1955) experience perforation (2 cases) occurred in their control group, and there was none in patients receiving cortisone Had all their patients received cortisone, these 2 might well have been attributed to the hormone In fact, perforation is a natural complication of ulcerative colitis, though opinions differ as to its frequency Rice-Oxley and Truelove (1950) put it at 3 1%, which agrees closely with the 3 4% of Ranken et al (1935), though they say this is a conservative estimate Lahey (1951) considered acute perforation uncommon and Bockus (1944) regarded it as rare Crile and Thomas (1951), however, thought it was the commonest cause of death in acute toxic ulcerative colitis All seem agreed that it is a hazard of the acute, fulminating type, and rare in the chronic disease with considerable fibrosis Before cortisone was discovered, it was realised that perforation in ulcerative colitis presented grave difficulties in diagnosis, being characterised by distension, rather than pain and rigidity For this reason, and because it is so commonly fatal, its incidence may have been underestimated, and more information is needed upon its frequency in control and cortisone treated groups

It would perhaps be wrong to assume that steroids greatly increase the risk of perforation, but what increase there is is unhappily greatest in the acute rapidly progressive case—in which the need for cortisone is greatest Perforation is certainly not a new complication, and the masking effect of the steroid hormones adds to the existing difficulty of diagnosis

Gastro-intestinal Hæmorrhage

In 2 of the 3 patients who died from this cause no lesion of the alimentary tract had previously been suspected The third had ulcerative colitis

Case 11 —A man, aged 25, had diarrhœa with bloody stools a year before his first admission in 1954, and was found to have moderately severe ulcerative colitis He responded well to blood transfusions, but quickly relapsed and was readmitted six weeks later He was given corticotrophin (total 500 mg) and remission was obtained He remained well until three weeks before his final admission in April, 1956, when he became feverish and the stools contained blood and pus No improvement followed bed rest and blood transfusion, and cortisone was started (100 mg daily by mouth) Five days later his abdomen became distended, hiccups appeared, and he vomited Bowel sounds were absent on the seventh day Perforation was diagnosed, cortisone was reduced, and gastric suction instituted He improved slightly but on the eleventh day he had a severe bowel hæmorrhage, and died within twenty four hours Necropsy revealed no perforation, but the colon was extensively ulcerated and contained much blood

Although contributing greatly to the anæmia of ulcerative colitis, hæmorrhage is not usually so massive as to cause death Lahey (1951) regarded hæmorrhage as "not infrequent" and said it might be severe and uncontrollable He implied that it was commoner than perforation, and was a particular hazard in young patients with acute disease Truelove and Witts (1955) had one massive hæmorrhage in their cortisone treated patients and none in their controls Evidence as to its frequency is scanty Bockus (1944) stated it was very uncommon (0 5% in adults and 1% in children) Brooke (1954) also regarded it as unusual, but mentioned that it might occasionally be severe enough to warrant emergency colectomy Neither Hurst (1935) nor Rice Oxley and Truelove (1950) mentioned its occurrence

Massive hæmorrhage does not seem to have been reported as a complication of steroid therapy for ulcerative colitis, and it is impossible to decide yet whether such therapy carries this added risk

HÆMORRHAGE FROM STOMACH AND DUODENUM

Neither of the 2 patients who died after hæmatemesis and melæna had a history of peptic ulceration

Case 12 —A roundsman, aged 55, was admitted to hospital in 1952 He complained of weight loss, conjunctivitis, and chest and joint pains for eight months There was purpura over the legs and ulcers on both ankles Significant findings were Hb 52%, white count 12,000 per c mm (10% eosinophils) and albuminuria Skin biopsy suggested polyarteritis nodosa He was treated with corticotrophin for six weeks and later discharged much improved on cortisone 25 mg daily He relapsed and was readmitted in 1953 He was again given corticotrophin and improved In the four months after discharge he received cortisone intermittently, and deteriorated slowly He was readmitted in August, 1953, and received corticotrophin 30 mg intramuscularly and cortisone 75 mg by mouth daily After nine months he was discharged on corticotrophin 60 mg daily, but diabetes developed and he was admitted for stabilisation He now showed the typical appearance of hypercortisonism Two days after admission abdominal pain and melæna developed, and he became shocked Despite blood-transfusions, he deteriorated, and laparotomy showed an acute gastric ulcer Partial gastrectomy was performed, but further bleeding followed and he died twelve hours later At necropsy there was an erosion in the stomach remnant, and a smaller one in the jejunum The appearances suggested an acute erosive or hæmorrhagic gastritis No evidence of active polyarteritis was seen on microscopy in the removed portion of stomach, skin, lungs, heart, kidney, or muscles

Case 13.—A priest, aged 44, was admitted during 1954 with pemphigus vulgaris Blisters had appeared in the mouth eight months earlier and spread to the trunk and limbs they disappeared when he was given cortisone 100 mg daily for a month, but reappeared on withdrawal On admission there was blistering of the skin and loss of nails The mouth and gums were heavily involved and there was continuous dribbling of bloodstained saliva Cortisone was immediately started, but details of the early treatment are not available Though there was some response, gradually increasing doses were required By December, 1954, he was receiving 1 05 g cortisone daily (750 mg orally, 300 mg I.M) and this continued until Jan 5, 1955, when the oral dose was reduced Diabetes developed on Jan 18 when he was receiving 800 mg daily Insulin was started four days later, and two days after this there was profuse hæmatemesis and melæna four pints of blood were given. Further hæmatemeses followed and he died on Jan 28 $7^{1}/_{2}$ pints of blood had been given Two days before death the dose of cortisone was 650 mg After the initial hæmorrhage, when the Hb was 31%, the platelet-count was low On Jan 26, the platelets had risen slightly, and on Jan 27 the count was 30,000 per c.mm (Hb 39%) On the day of death, platelets numbered 50,000 per c mm and the Hb was 64% At no time was purpura observed Necropsy could not be obtained

Both patients were receiving high doses and showed signs of hypercortisonism Indeed, in both diabetes developed shortly before the hæmorrhage occurred In case 13 the dose was larger than any previously used at Guy's Hospital In case 12 there was a hæmorrhagic gastritis, and the jejunal erosion may have developed in the few hours' survival after gastrojejunostomy If so it would be interesting to know whether this was the result of a remarkably corrosive gastric juice from the stomach remnant or of diminished mucosal resistance due to corticotrophin Polyarteritis cannot be blamed in the absence of histological changes, and cortisone seems the most likely cause of death

There is no proof of the cause of hæmorrhage in case 13 The marked thrombocytopenia was originally suggested, but cortisone is usually considered to cause a rise in platelets, though a slight and variable depression may follow corticotrophin (Warren et al 1953), lasting up to forty eight hours and resembling the immediate fall after an operation Low platelet-counts have been recorded after massive gastro intestinal hæmorrhage (Desforges et al 1954) occasionally very low counts (50,000 or below) persisted if there was further bleeding Severe platelet depression may follow large transfusions for hæmorrhage (Krevans and Jackson 1955), and significant thrombocytopenia developed in 4 of 13 patients who received up to 5 litres of blood The same mechanism was probably responsible for the platelet depression in case 13 and it has not been attributed to cortisone In the absence of necropsy proof, and in view of the great similarity to case 12, death has been attributed to hæmorrhagic gastritis induced by cortisone

Hæmorrhage and perforation complicating ulcers reactivated or induced by steroid hormones are well recognised Gray et al (1951) showed that cortisone and corticotrophin might considerably increase gastric secretion and uropepsin excretion, in a patient who died from massive hæmorrhage from a duodenal ulcer, necropsy showed a hæmorrhagic gastritis Sauer et al (1953) recorded 3 cases of peptic ulcer, in 2 of which there was severe hæmorrhage These 3 patients had signs of hypercortisonism, but peptic ulcer may develop on comparatively small doses a patient developed both gastric and duodenal ulcers whilst receiving 50 mg cortisone daily (Davis and Zeller 1952) The increased gastric secretion (Gray et al 1951) is an attractive explanation for ulceration during therapy, but the doses used were extremely large, corticotrophin 120–160 mg or cortisone 200–500 mg daily These are comparable with the doses in cases 12 and 13, but far greater than in many reported cases of ulcer Hirschowitz et al. (1955) found no increase in gastric secretion in healthy students given 50 mg corticotrophin daily for six days, and in 1 an ulcer developed after five days A gastric ulcer also appeared in a student who had had small doses of steroid hormones intermittently (Hirschowitz et al 1956) This student had no increase in gastric acidity, and Hirschowitz et al consider that by no means all ulcers, either naturally occurring or hormone-induced, are the result of increased gastric secretion, but decreased mucosal resistance may play a more important part

The danger of peptic ulceration during steroid therapy lies in its liability to attack previously normal persons, and to cause hæmorrhage and perforation without warning Cases 12 and 13 resemble those of Gray et al (1951) in that they were having very large doses, but there is no evidence about their gastric secretion

Deaths from Other Causes

PULMONARY EMBOLISM

Case 14—A housewife aged 55, was admitted because of bronchial asthma, worsening in the previous six weeks There was slight cardiac enlargement, blood-pressure 160/110 mm Hg She had severe varicose veins Daily intravenous infusions of corticotrophin in glucose were given 30 mg for two days, 20 mg for four days, 15 mg for one day, and 10 mg on the last day Her asthma improved greatly, but the day after the last dose she complained of precordial pain, became pale and pulseless, and was soon dead Necropsy showed a massive embolus obstructing the main pulmonary artery The deep calf veins were thrombosed in both legs

There are conflicting reports of the effect of cortisone and corticotrophin on blood-clotting Cosgriff et al (1950) reported that the venous clotting-time and heparin-retarded clotting time were shortened, but there was no change in prothrombin-time, fibrinogen-B content, or protamine titration Monto et al (1950) found variable changes in coagulation, including in some patients an increase in circulating heparin during therapy Cosgriff (1951) encountered 48 thromboembolic incidents among 700 patients receiving steroid hormones and considered this incidence greater than expected, but Russek et al (1954) observed no complications in 100 patients treated with cortisone for various cardiovascular conditions, including angina pectoris and myocardial infarction

The incidence of thromboembolic complications during steroid therapy at Guy's Hospital has not appeared abnormal, and it is impossible to say whether the death in case 14 was due to corticotrophin An embolus shortly after a course of corticotrophin is interesting in view of the observation of Hume and Moore (1952) that thrombophlebitis was perhaps more likely to follow cessation of the hormone, and this might be analogous to the thrombophlebitis after surgical operations, when adrenocortical activity is lessening or has returned to normal Margulis's (1952) observation that circulating heparin increased during corticotrophin therapy and afterwards fell below normal may explain this If death is to be attributed to corticotrophin in case 14, this may have been the mechanism

HYPERSENSITIVITY TO CORTICOTROPHIN

Case 15—A man, aged 59, who had had ankylosing spondylitis for twenty-five years, was admitted for trial of corticotrophin He had had radiotherapy in 1936 *Bilateral sympa-*

thectomy was performed in 1946 for thromboangiitis obliterans. On admission, there was complete rigidity of the spine and neck, chest expansion was 1 in., and the temporomandibular joints were almost fixed. A few inconstant râles were heard at the left lung base. Because of his abject condition, corticotrophin was tried (25 mg. daily in glucose by intravenous drip). After two days, improvement was remarkable, and he could open and close his jaws normally, but during each infusion he complained of dyspnœa, and his temperature rose to 99°F. The dyspnœa became worse during the next two infusions and he produced a little tenacious sputum. Rhonchi and râles were heard over the chest. The symptoms subsided immediately the corticotrophin was finished, and none was given on the next day. On the sixth day, corticotrophin had to be stopped because of dyspnœa, and despite apparent improvement he was found dead twelve hours later. At necropsy there was slight right ventricular enlargement (heart 145 g.), a little free fluid was present in both pleural cavities, and the trachea and bronchi contained much tenacious mucoid sputum. There was no evidence of infection or of pulmonary œdema. The pelvic colon contained a small adenocarcinoma, without metastases, and there was a hæmorrhagic phæochromocytoma in the left adrenal gland.

Hypersensitivity to corticotrophin, occasionally fatal, has been reported (Feinberg et al. 1951, Wilson 1951, Brown and Hollander 1952, Stevenson 1952, Hill and Swinburn 1954). The sensitivity may be to pork or beef protein derived from the source of preparation or to the hormone itself. A previous dose or course of corticotrophin has usually been given and the reaction may be immediate or delayed (Thorn et al. 1953). The reported reactions include pruritus, angioneurotic œdema, or urticaria, particularly at the site of intramuscular injection, asthma and bronchospasm, and severe circulatory collapse, often with rigors and abdominal pain.

Death in case 15 seems undoubtedly due to corticotrophin, but the exact cause is less obvious. No skin rash was observed, and sensitivity tests were not performed. The picture suggested bronchial asthma, and there is little doubt that it appeared to subside each time corticotrophin was stopped. Pulmonary œdema from sodium and fluid retention in a patient with considerably diminished chest expansion was a possible explanation, but no rise in venous pressure was observed, and the necropsy findings did not suggest this mechanism. Whether the unsuspected phæochromocytoma in any way contributed to death is not known, but it seems unlikely. Death has been tentatively attributed to hypersensitivity to corticotrophin. This case emphasises Wilson's (1951) warning that the hormone should be stopped immediately at any sign suggesting hypersensitivity.

CARDIAC FAILURE

Case 16.—A housewife, aged 53, was admitted because of breathlessness for nine years and recent "blackouts" on exertion. She suffered from Raynaud's phenomenon, and had undergone bilateral cervical sympathectomy and amputation of the left 5th finger. She had signs of scleroderma. No cardiac enlargement was detected, but the pulmonary 2nd sound was increased, and the venous pressure was slightly raised. A chest radiograph showed fine reticulation over the lung fields and enlargement of the pulmonary artery and heart. Scleroderma with probable involvement of heart and lungs was diagnosed. Cortisone (100 mg. daily) was given, and the hands appeared much improved, but she was readmitted six weeks later in heart-failure. Cortisone was discontinued and treatment with digitalis and mersalyl started. She died in cardiac failure seven weeks after cortisone was stopped. Necropsy showed enlargement of the right ventricle and dilatation of the tricuspid ring. The pulmonary artery was dilated, and its walls showed plaques of atheroma. The lungs were tough but not grossly abnormal. A small ulcer was present in the stomach. Microscopical changes of scleroderma were seen in the skin, but not in the heart or in the lungs, which were emphysematous only.

This patient had pulmonary hypertension, presumably secondary to her emphysema, with the resulting symptoms and signs—e.g., effort syncope. In retrospect it is clear from the radiographs that the right ventricle and pulmonary artery had enlarged during the previous year and as cardiac failure developed within three weeks of starting it, cortisone must be assumed to be the precipitating factor. Since the fluid-retaining properties of cortisone and corticotrophin are so well known, few fatalities are likely from their use in patients with established or threatened failure. Although prednisone (Nabarro et al. 1955) and prednisolone usually cause less electrolyte disturbance, they may still precipitate failure and should be avoided when this risk is present.

RUPTURE OF THE AORTA

Case 17.—A schoolgirl, aged 15, was admitted for persistent pyrexia and indifferent health for a year. Seven weeks earlier her nose became red, painful, and swollen. Listlessness, sweating attacks, and remittent fever (99–102°F) developed. Both elbows became swollen and her appetite was poor. Several antibiotics had been given without effect. There was a red papular lesion over the nose, and slight faucial inflammation. The only other abnormal finding was an apical systolic murmur.

Investigations.—Chest radiograph normal. White count 15,800 per c.mm. (polymorphs 73%, eosinophils 1%). Erythrocyte sedimentation rate (Westergren) 135 mm. per hr. No L.E. cells in peripheral blood. Sternal marrow normal. Blood agglutination negative. Mantoux (1 in 1000 O.T.) negative. Stools normal. Serum-proteins, 6·6 g. per 100 ml. (albumin 3·0 g., globulin 3·6 g.); electrophoresis, diminished γ, but raised α_2 globulin. Muscle biopsy normal.

The rather imprecise diagnosis of "a collagen disease" was made and cortisone given by mouth (6·3 g. over twenty-six days). Symptoms were much improved and the pyrexia was abolished, but the E.S.R. remained high (118 mm. per hr.). On the twenty-sixth day of treatment she complained of vague chest pain and later severe substernal pain. At 5 P.M. she became pale and shocked, rapidly going blind. An electrocardiogram was normal. The signs suggested hæmorrhage but none could be detected. She died at 6 P.M. A fusiform dilatation of the descending thoracic aorta was found to have ruptured into the left pleural cavity. There were smaller aneurysms in the abdominal aorta and common iliac vessels. Many inflammatory cells were seen in the subintimal layer of the aorta, extending into the media near the aneurysms. The subintima of the coronary arteries contained similar lesions. The histological diagnosis was "an acute arteritis of unknown ætiology" affecting the aorta and main vessels.

The main problem here is to decide whether cortisone precipitated rupture of an already damaged aorta or was conceivably responsible for all the post-mortem histological changes. The possible production of fibrinoid necrosis by cortisone (Lunseth et al. 1951), and the sequel of visceral infarction in vessels affected by polyarteritis (Schick et al. 1950, Sharnoff et al. 1951) have already been discussed in connection with intestinal perforation. Severe mesenchymal reactions (with lesions indistinguishable from polyarteritis nodosa) have been observed in patients receiving large doses of steroid hormones for rheumatoid arthritis (Polley 1956). This girl clearly had a severe illness, compatible with a progressive arteritis, long before cortisone was given. Aortic weakening and dilatation had begun before treatment was started, for re-examination of the radiographs shows that, though the descending aorta appeared normal on admission, dilatation of the retrocardiac portion had begun seven days before cortisone was started, and was considerable on the last film, nine days before death. This change was not appreciated at the time. Cortisone may have precipitated rupture, but disorganisation of the vessel wall was so widespread that rupture appears to have been inevitable. This death was not, therefore, attributed to cortisone.

CHRONIC HYDROCEPHALUS DUE TO CYSTICERCOSIS

Case 18.—A man, aged 45, who had lived in India, was investigated for recurrent headaches with vomiting. Radiographs showed calcification in the limb muscles and an air encephalogram showed a shadow in the roof of the 3rd ventricle. Cysticercosis was diagnosed, and cortisone started because of the suggestion that the attacks might represent

DETAILS OF TREATMENT IN PATIENTS WHO DIED DURING STEROID THERAPY

Case no	Age and sex	Clinical diagnosis	Duration of steroid therapy	Dose at time of complication	Cause of death	Whether attributed to steroid therapy
1	23 F	Scleroderma	18 months Intermittent cortisone, usually 100 mg daily	100 mg daily Stopped 10 days previously	Infection (pneumonia) No necropsy	Yes
2	50 M	Rheumatoid arthritis	3½ months Cortisone 100 mg daily	150 mg daily	Infection (pneumonia) Necropsy	Yes
3	[illegible]4 M	Polyneuritis	11 months Corticotrophin 40–60 mg for 8 months Cortisone 200 mg daily for 3 months	Cortisone 200 mg daily	Infection (pneumonia) Necropsy	Yes
4	47 F	Polyarteritis nodosa	13 months Cortisone 150 mg for 7 months, 200 mg for 3 months Prednisolone 45 mg daily for 2 months	Prednisolone 45 mg daily	Infection (peritonitis followed by pneumonia) Laparotomy no necropsy	Yes
5	[illegible]6 M	Scleroderma	Cortisone 100 mg for 18 days 75 mg for 19 days	Cortisone 75 mg daily	Probably infection ? Septicæmia No necropsy	Probable
6	[illegible] M	Dermatitis of unknown ætiology	5 months Corticotrophin 30 mg daily and for last 2 months cortisone 200 mg daily added	Corticotrophin 40 mg cortisone 200 mg, both daily	Infection (bronchopneumonia) Necropsy	Unlikely (considered terminal event in the disease)
7	48 F	Scleroderma	Approx 2 months Cortisone 100 mg daily	Cortisone 100 mg daily	? Fulminating infection No necropsy	Probable No proof
8	67 F	Temporal arteritis	4 months Prednisolone 20 mg daily	Prednisolone 20 mg daily	Perforation of colon due to diverticulitis Post-op adrenal failure Necropsy	Yes
9	51 F	Polyarteritis nodosa	15 days Corticotrophin 40 mg daily for 13 days Cortisone 200 mg for 2 days	Corticotrophin 40 mg daily	Perforation of ileum Necropsy	Possible
10	75 M	Ulcerative colitis	12 days Corticotrophin (total 420 mg)	Corticotrophin 40 mg daily	Perforation of colon Necropsy	Possible
11	25 M	Ulcerative colitis	8 days Cortisone 100 mg daily	Cortisone 100 mg daily	Hæmorrhage from colon Necropsy	Possible
12	[illegible]5 M	Polyarteritis nodosa	1 year Corticotrophin and cortisone various doses	Corticotrophin 60 mg daily	Massive gastro-intestinal hæmorrhage Necropsy	Yes
13	45 M	Pemphigus vulgaris	Approx. 8 months Cortisone up to 1 g daily	Cortisone 750 mg daily	Massive gastro-intestinal hæmorrhage No necropsy	Yes
14	55 F	Bronchial asthma	8 days Corticotrophin 30–10 mg daily	Corticotrophin 10 mg daily	Pulmonary embolism Necropsy	Unlikely
15	59 M	Ankylosing spondylitis	3 days Corticotrophin 25 mg daily	Corticotrophin 25 mg daily	? Hypersensitivity to corticotrophin Necropsy	Yes
16	53 F	Scleroderma	6 weeks Cortisone 100 mg daily	Cortisone 100 mg daily	Congestive heart failure Necropsy	Yes
17	1[illegible] F	Acute necrotising arteritis	26 days Cortisone 150–300 mg daily	Cortisone 300 mg daily	Rupture of [illegible] Necropsy	No
18	[illegible]2 M	Cerebral cysticercosis	Approx [illegible]½ months Cortisone 1[illegible]0–300 mg daily	Cortisone 150 mg daily	Hydrocephalus from cerebral cysticercosis Necropsy	No

reaction to foreign protein, since the cerebrospinal fluid contained many eosinophils during these attacks. Later attacks were possibly improved by increasing the cortisone, but in one of these he became unconscious and despite ventricular puncture died. Necropsy confirmed the presence of cysticercosis.

There seems no reason to believe that cortisone in any way hastened or caused death, and it has not been held responsible.

Conclusions

Steroid therapy can be fairly blamed for 9 of the 18 deaths and was probably responsible for 2 more (see table). In 2 patients therapy has not been held responsible and it seems unlikely to have played a part in a further 2. In the remaining 3 death was quite possibly hastened or contributed to by cortisone or corticotrophin, for reasons already discussed. Of the 11 patients whose death has been attributed to steroid therapy 5 at least were suffering from diseases often fatal. 2 of the 3 patients whose death may have been precipitated by therapy were gravely ill, one with polyarteritis nodosa, the other with fulminating ulcerative colitis. It would be quite wrong, therefore, to assume that cortisone or corticotrophin was responsible in every case, and to do so would exaggerate the risks of steroid therapy. It is not possible to assess accurately the incidence of fatal complications, for though 11 deaths certainly resulted from treatment the exact number of patients receiving steroid hormones is not known (it is approximately 500). Even with accurate figures, such a crude incidence would be of doubtful value since it ignores the various diseases treated.

In this series fatal complications have not been related to size of dose or duration of treatment, though clearly the longer a patient receives steroid hormones the longer he is at risk. The minimum time for serious complications to appear is very short, and one of Page's (1954) patients died from pneumonia only seven days after starting corticotropin. Cases 10 and 11 (ulcerative colitis) had fatal complications twelve and eight days respectively after starting treatment. In cases 12 and 13 (death from gastro-intestinal hæmorrhage) very high doses were given for long periods, but severe hæmorrhage has been reported (Davis and Zeller 1952) after only 50 mg cortisone daily, and it would be unwise to draw any conclusions from these 2 patients.

Infection and gastro-intestinal perforation and hæmorrhage have been the commonest fatal complications as they have been in other published series It is hard to see how the risk of infection can be prevented, though patients with tuberculosis and perhaps other chronic infections should be excluded from treatment, save in very special circumstances Similarly patients with a history of peptic ulcer should be excluded, but steroid hormones can cause ulceration in some normal subjects, so that this complication cannot entirely be prevented Death could probably have been prevented in some cases in this series (particularly those due to infection, and the postoperative death) had the vital importance of continuing or increasing the dose of cortisone or corticotrophin during the period of stress been fully appreciated The masking effect of the steroid hormones will always make the detection of an infection difficult, and it is our practice to give large doses of antibiotics at the slightest hint of infection In cases of doubt such a patient is admitted to hospital for observation, and all patients are warned that they must immediately call in their doctor should any untoward malaise or symptom occur Even so, occasional fulminating cases, like those reported by Page (1954), are still likely to happen The patient away from home or who is admitted to another hospital after an accident runs an increased risk unless the need for extra cortisone is appreciated

The development of compounds similar in anti-inflammatory effect to cortisone will continue for prednisone and prednisolone it has been claimed that the unwanted action on fluid and electrolyte balance is much less than that of cortisone As Nabarro et al (1955) have warned, only the less important side effects are removed or diminished with these compounds, the serious ones of adrenocortical suppression and risk of infection remain This false security of prednisone and prednisolone may mean that they are more freely prescribed when there is no real need It is unlikely that compounds will be produced which retain considerable anti rheumatic and anti inflammatory properties without the risk of infective complications and without adrenal suppression

As with all other methods of treatment which have at first sight appeared miraculous, the limitations of the corticosteroid hormones are now being appreciated, particularly with regard to the possibility of serious complications But other forms of treatment have their risks, and it would be a great pity if the dangers of steroid therapy were overemphasised They must, however, be understood, and each physician may have his own ideas as to the best use of corticosteroids It is unwise to embark upon steroid therapy without adequate means for careful and regular supervision of the patient, and unless real benefit can be anticipated As Polley (1956) has recently put it, "For optimal therapeutic value, use of these hormones should be supervised by physicians who have familiarised themselves with its intricacies in the same thorough manner that they would consider necessary in undertaking any complicated medical or surgical treatment"

Summary

In 18 deaths associated with steroid-hormone therapy, infection was the commonest cause (7 cases), and gastro-intestinal hæmorrhage and perforation were each responsible for 3 deaths

Steroid therapy was considered directly responsible for 11 deaths, and probably hastened death in 3 more In 4, death was not the result of this treatment

There is a serious risk of adrenal failure in patients who encounter added stress during steroid therapy Under such circumstances, doses must be increased and antibiotics given in large amounts

Steroid therapy inevitably carries some risk, and regular and careful observation of all patients is imperative

I wish to thank Dr A H Douthwaite, Dr A C Hampson Dr W N Mann, Dr M J McArdle, Dr K S MacLean, and Dr E J Moynahan for permission to study patients under their care, and to make use of case histories in this report. I am greatly indebted to Dr Ian Milne, H M Coroner for South London, and to Dr F E Camps for allowing me to publish details of the post mortem findings in case 12, and to Dr Russell Hughes, of Rhyl, for his helpful notes concerning case 1 Finally, I should like to express my appreciation to Dr MacLean, assistant director, Department of Medicine, Guy's Hospital, for his encouragement and valuable help and advice on numerous occasions

From the Department of Biochemistry, University of Melbourne

THE plasma insulin level in man has been studied by Bornstein (1950), Bornstein and Lawrence (1951), Groen et al (1952), and Vallance-Owen and his colleagues (Vallance Owen and Hurlock 1954, Vallance Owen et al 1955) In all cases difficulty was caused by one of two factors with the technique used by one of us (J B) many laboratory animals either died during preparation or had to be rejected because of instability of their blood-sugar level , and the diaphragm technique used by other workers, notably Groen et al (1952), Vallance Owen and Hurlock (1954), and Randle (1956) lacks precision

An added difficulty in estimating plasma insulin is the fact that, in some diabetics, insulin antagonists can mask the presence of plasma-insulin (Bornstein and Lawrence 1951, Vallance Owen et al 1955, Field and Stetten 1956, Hampton et al 1956) Bornstein and Park (1953) and Randle and Young (1956) also found a labile inhibitor in the plasma of alloxan-diabetic rats

Attempts to simplify estimations by using small animals—e g , mice—are handicapped by the fact that glucose is injected together with plasma , thus the injection of 1 0–4 0 mg of glucose in 1 ml of plasma into an animal with a total blood volume of 1 5–2 0 ml may completely mask any fall of blood sugar level due to plasma insulin and will certainly decrease the observed fall

In view of these considerations we tried to concentrate insulin from plasma, thus freeing it from glucose and enabling us to give in a small volume the equivalent of much larger amounts of plasma The administration of such concentrates of insulin should then make it possible to design an assay using more stable animal preparations than before

We also hoped that, in the process of fractionation, the antagonists would either be destroyed or separated from the insulin fraction , but, since the nature of the antagonists was unknown, we could not plan to do so

We describe here the fractionation process and present the evidence that the fraction obtained contains insulin A study of normal, diabetic, and insulin resistant diabetics shows that the method used separates insulin from its antagonists

Methods and Material

In all the preliminary experiments insulin labelled with ^{35}S by sulphation according to the method of Stadie et al (1952) was added to the plasma to facilitate fractionation

The biological activity of all the fractions obtained was tested on the rat diaphragm at 200 mg of glucose per 100 ml by the technique of Brown et al (1952) A fraction was only considered active if the acceleration or inhibition observed was statistically significant ($P = 0\ 05$)

In all the cases freshly obtained normal human plasma was used, and clotting was prevented with heparin

Reagents

Analytical reagent (A R) absolute ethyl alcohol was redistilled

Sulphur free toluene (B D H) was found satisfactory If it was not available, toluene was freed from all sulphur-containing compounds by standard methods (Weissberger 1950)

A R grade *n*-butyl alcohol was repeatedly shaken with A R grade 5% sulphuric acid, refluxed with caustic soda and then redistilled, only the middle third of the fraction boiling between 117°C and 118°C being used

A R grade acetone was used throughout

It is essential to use reagents of the highest grade of purity because reducing substances in the solvents can inactivate insulin

Technique

To 1 vol of freshly obtained plasma were added 4 0 vol of ethyl alcohol, 0 4 vol of toluene, and 0 4 vol of *n*-butyl alcohol The pH was then adjusted with HCl to pH 1 5 (indicator paper), and the mixture was shaken for an hour Then the mixture was centrifuged, the supernatant fluid set aside, and the residue re extracted four times, for an hour at each extraction, with a solvent mixture consisting of 1 vol of 0 04 *M* sodium acetate, 4 0 vol of ethyl alcohol, 0 4 vol of toluene, and 0 4 vol of *n*-butyl alcohol, the pH being adjusted as before

The five supernatant fluids were combined, and acetone was added to give a final concentration of 83% acetone This precipitated all the protein contained in the extract

Experiments with added ^{35}S-labelled insulin showed that about 85% of all counts were present in this fraction (table I)

TABLE I—RECOVERY OF COUNTS IN PRIMARY EXTRACTION INSULIN LABELLED WITH ^{35}S ADDED TO PLASMA

Experiment no	Counts added	Counts recovered		% recovery	% counts in extract
		Extract	Residue		
1	21 950	19 600	3370	104 6	85 5
2	21 950	19 050	3220	101 5	85 5
3	24,000	20 132	2895	95 5	87
4	24 000	20,325	3870	100 8	84
Mean				100 6	85 5

The residue (residue A) and the extract were then dried in vacuo and stored

To test the biological activity of such extracts a fixed volume of 0 15 *M* saline solution (usually half the original plasma volume) was added, the pH adjusted to 2 5–3 0, and the mixture stirred for 30 minutes * The supernatant fluid was collected by centrifuging at high speed (8000 *g*) and the volume accurately measured to allow for correction in terms of original plasma volume The extract was then neutralised and incorporated in Krebs Henseleit buffer to give a plasma equivalent of 0 4 ml of original plasma per ml of buffer No glucose was found in the dissolved extract A considerable portion of the protein had been denatured and was insoluble (residue B) This was suspended in saline solution and tested on the rat diaphragm

Protein estimations showed that the extract contained about 2 5% of the original protein (table II), and all the insulin-like activity was contained in this extract (table III)

TABLE II—PROTEIN CONTENT OF INSULIN EXTRACTS OF PLASMA

Extract no	Total protein in sample (mg)	Extract protein (mg)	% extracted
1	69 0	1 014	1 47
2	61 0	1 268	2 08
3	66 5	2 290	3 44
4	61 0	1 960	3 22
Mean			2 55

Protein estimations according to method of Lowry et al (1951)

To determine whether the acceleration so obtained in utilisation of glucose was due to insulin or was non-

---

* In earlier experiments the dry protein powder was stirred for a much longer time to bring a greater amount of protein into solution but much colloidal material became suspended, and this produced irregular results

TABLE III—ACTIVITY OF VARIOUS FRACTIONS OBTAINED FROM EXTRACTION PROCEDURE WHEN TESTED ON RAT DIAPHRAGM

Fraction	Change of rate of utilisation of glucose by rat diaphragm (mg per g per hr)	
	No of diaphragms	Change in rate ±S E M
Extract	45	+1 14 ±0 18
Residue B	14	−0 20 ±0 17
Residue A	28	−0 60 ±0 16

For effect of extract n = 44, T = 6 33, P <0 001
For effect of Residue A n = 27, T = 3 75 P <0 01
All results are expressed as either acceleration or inhibition of control rate

specific, extracts were prepared and divided into four parts One part was treated with alkali and one part with cysteine according to the technique of Sutherland and Cori (1948) After inactivation such inactivated extracts were dialysed against Krebs Henseleit buffer To avoid differences due to losses during dialysis, two remaining fractions were dialysed in parallel To prevent variations due to traces of cysteine or of alkali in the extract, *an identical quantity of these reagents was* added to Krebs Henseleit buffer, and this was then dialysed in exactly the same way as the extracts, and used for the incubation of the control hemidiaphragms Diaphragm experiments showed that both alkali and cysteine inactivated such extracts (table IV)

The technique of investigation thus established was applied to the study of insulin in the plasma of healthy people and patients with ordinary diabetes mellitus and with insulin-resistant diabetes mellitus

The method of study was the rat-diaphragm technique (Brown et al 1952) applied to crude plasma, the extract, and residue A

22 people were investigated by these methods 7 healthy adults, aged 23–37, 8 diabetics, aged 17–71, of whom 1 showed insulin resistance, and 7 patients in diabetic coma, including 4 with insulin resistance In all the cases 0 4 ml plasma or its equivalent was used

The sensitivity of the rat diaphragms to 1 milliunit (0 001 unit) of crystalline insulin was tested at intervals throughout the investigation

Results

The results are expressed as the change in glucose utilisation in mg per g of muscle per hr caused by adding the test substance to the buffer Table V shows that in all the cases where a statistically significant acceleration was observed as the result of adding crude plasma, a similar significant acceleration was seen when extract was used

It also shows that the residue from the extraction process never accelerated the utilisation of glucose by the diaphragm, and that in most cases a statistically significant inhibition was observed

The experiments on cases of untreated diabetes mellitus bear out findings previously reported (Bornstein and Lawrence 1951) that the patients fall into two groups those with and those without available plasma-insulin

TABLE IV—EFFECT OF CYSTEINE AND OF ALKALI ON ACTIVITY OF EXTRACTS

Extract no	Change in rate of utilisation of glucose by paired hemidiaphragms			
	No of diaphragms	Change in rate (mg of glucose per g)	S E M	P
1	8	+1 19	0 2	0 001
1A	8	−0 66	0 36	0 2
2	7	+1 61	0 34	0 01
2C	7	−0 14	0 31	

Extract 1A after treatment with alkali and dialysis
Extract 2C after treatment with cysteine and dialysis

It is of considerable interest that in no case of diabetic coma was "free" insulin found in the plasma, although, in some of these, very large amounts had been administered in the previous twenty-four hours In all such cases—i e, where insulin had been administered—the extract showed insulin activity Patients who had been stabilised on insulin showed insulin present in their plasma

Discussion

The distribution of radioactivity and biological activity after extraction, together with the fact that the extracts were inactivated by alkali and by cysteine, strongly suggests that the acceleration observed was due to insulin Strong support is lent to this view by the more recent finding (unpublished) of C W Baird and J Bornstein that such extracts depress the blood sugar level of adrenalectomised alloxan-diabetic mice Both the diaphragm experiments and the preliminary assays done on the prepared mice suggest that the plasma insulin level is about 1–2 milliunits of insulin per ml of plasma in healthy adults after a meal

TABLE V—COMPARISON OF EFFECT OF CRUDE PLASMA, EXTRACT, AND RESIDUE A ON RATE OF GLUCOSE UTILISATION BY RAT DIAPHRAGM

Experiment no	Sex	Age	Insulin in previous 24 hr	Change in rate of glucose utilisation (mg per g of muscle per hr) with S E M material added

Insulin (1 milliunit)						
a				1 9 ±0 39		
b				1 6 ±0 34		
c				1 1 ±0 26		
d				1 1 ±0 27		

In all experiments where standard error is given at least 6 diaphragms were used for the test Where S E M is not quoted only 4 were used owing to lack of material

Results marked with an asterisk were not statistically significant

[1] Patient stable on 24 units a day, insulin resistant 6 years previously

[2] Patient insulin resistant last dose of insulin 24 hr before test

[3] Patient insulin resistant before coma stable on 1000 units a day

0 4 vol of plasma or its equivalent was used in every case

The results obtained in the diabetics (table V) show that such patients fall into two groups those with and without available insulin, cases 11 and 12 being typical juvenile diabetics showing no insulin in either plasma or extract These two patients were later stabilised on 28–36 units insulin a day

Wrenshall et al (1952) have shown that the pancreas of most diabetics aged more than 25 contains insulin However, Bornstein and Lawrence (1951) and Bornstein and Trowbell (1951) found that, in patients with severe diabetes in this age group, the presence of insulin could not be demonstrated in crude plasma So far patients of this type have not been studied by the present technique, but case 21 strongly suggests that such patients may be secreting insulin masked by antagonists in the plasma This patient, a woman aged 29, was seen in coma after having omitted insulin for five days Her plasma actively inhibited the rat diaphragm, but the extract accelerated its utilisation of glucose to a degree seen in healthy people, thus indicating the presence of insulin

Cases 18–22 show that, in diabetic coma, insulin can be present in the plasma but is masked by an antagonist or antagonists, which can be separated by the fractionation process used It is of interest to speculate whether the antagonist is binding insulin in such a way that it is not available to the cell or the antagonist is acting on some enzyme system This masking of the insulin action confirms the results of Vallance-Owen et al (1955) and Field and Stetten (1956)

The nature of the inhibition produced by the residues obtained is of the greatest importance It is, of course, possible that such residues are inhibitors only because they contain toxic products arising from denaturation of proteins during extraction However, in case 22, intravenous injection of the residue in the same quantity as used on the diaphragm into each of a group of 20-g mice protected these animals against hypoglycæmic convulsion induced by a standard dose of insulin, thus suggesting that the effects observed may be due to a specific inhibitor If the effect of such residues is specific, it seems that, in healthy people, there is a balance between insulin and its antagonists in the plasma, and that this balance is upset when insulin resistance is present, whether the patient is in coma or not, as in cases 15–22

Furthermore there seem to be two kinds of antagonist one which is destroyed by extraction (cases 17 and 19), and another which is stable in this procedure (cases 15 and 20–22) It is impossible to state whether the labile antagonist is identical with that described by Bornstein and Park (1953), Krahl and Bornstein (1954), and Randle and Young (1956), but the stable fraction is probably the same as that described by Field and Stetten (1956)

Summary

A technique for extracting insulin from plasma is described

This technique, applied to diabetics, showed that, in diabetic coma, insulin can be present in the plasma, but its activity is masked by antagonists

The implications of the results are discussed

We wish to thank Dr Ewen Downie and Dr H P Taft for permission to study their patients, Miss J Hill for invaluable technical assistance, and the Australian National Health and Medical Research Council and Eli Lilly and Company for financial support

DUODENAL ULCER

TREATED BY GASTRO-ENTEROSTOMY WITH VAGOTOMY

F Denis Hindmarsh
T D, M S Durh, F R C S
ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY,
NEWCASTLE UPON TYNE

In eight years, at the Royal Victoria Infirmary, I have treated 197 patients by vagotomy and posterior gastrojejunostomy according to principles previously described (Hindmarsh 1954) This series of 197 cases of duodenal ulcer comprises all those operated on at this hospital by this method except those treated in the past twelve months

Ætiology of Duodenal Ulcer

There is much evidence that the main factor in the causation of duodenal ulcer is the presence of unbuffered gastric acid combined with the free pepsin produced by psychic or nervous stimulation

The flow of gastric juice, under nervous stimulation, may in itself produce an ulcer This has been shown by work on dogs in which the œsophagus was dissociated from the stomach and anastomosed to the jejunum (Winkelstein et al 1956) The vagal nerves were kept intact and a considerable proportion of these dogs developed ulcers which had the same complications as duodenal ulcer in man and were pathologically similar to such ulcers

That peptic ulcer can be formed by unused secretion of gastric juice was shown in a case of reduplication of the bowel, when an ulcer developed on the antimesenteric border of the normal bowel just opposite the small communication connecting it with a gastric reduplication (fig 1) in a child, aged 3 years, admitted with generalised peritonitis from perforation of the ulcer

To Dragstedt and his colleagues belongs the main credit for introducing vagotomy as a means of reducing excessive peptic secretion, but a recent article emphasises the importance of avoiding the secondary effects of this operation (Oberhelman and Dragstedt 1955) The views expressed in that article are in accordance with my own clinical experience of combining vagotomy with gastro enterostomy

The Present Series

Selection of Material

The patients selected for this operation have been those (of whatever age) in whom chronic ulcer or scarring was demonstrated radiologically and confirmed by laparotomy The length of history was not considered important, because sometimes a chronic ulcer may be found after a very short period of symptoms Many of the cases, however, presented with symptoms which had been present many years—occasionally twenty-five or thirty Acute hæmorrhage—in which partial gastrectomy may save life—is a definite contra indication to this operation, but the need for emergency gastrectomy would diminish if more chronic ulcers were submitted to surgery at an earlier stage

Review of Results

Each patient was interviewed at the end of the first year and was later sent circular letters Of the 197 patients operated on, 1 died after the operation and 2 subsequently from cerebral hæmorrhage, and 1 was not traced, leaving 193 for review, all of whom have been reviewed in the last six months These were graded according to the scheme devised by Visick (1948), those without gastric symptoms being placed in grade I

If symptoms were present, their severity was assessed at an interview (see table) Grade II means that symptoms were slight, grade IIIS that symptoms were occasionally troublesome but controlled, grade IIIU that symptoms were troublesome and uncontrolled, and grade IV that the ulcer had definitely recurred Such assessment is always open to error because the grateful patients minimise their symptoms Those with symptoms were not included in grade II, however, unless the patient said that his symptoms were slight and did not cause any loss of work and his weight was steady Grade IIIS consists of patients who were much improved but lost work because of gastric symptoms, which were occasionally troublesome Loss of weight seemed *directly* attributable to the gastric operation in only 3 cases In 2 others pulmonary tuberculosis developed, and it was thought that loss of weight was due to the tuberculosis

The Operation

Most surgeons who have performed vagotomy by itself are familiar with its unpleasant side effects The most troublesome of these are flatulence with foul gaseous eructations, a sense of unpleasant fullness, vomiting, and very often diarrhœa Of a small series of 20 cases of duodenal ulcer which I treated by vagotomy alone, gastric ulceration occurred in 3 I regarded this as due to gastric retention and the symptoms were satisfactorily controlled when adequate drainage was provided by gastro enterostomy

In the present series of 193 cases the dual aim was to perform a complete vagotomy and to provide good drainage

Complete vagotomy—the first step—may be done without dividing the left coronary ligament to the liver, which can be drawn forwards to expose the gastrophrenic ligament The posterior (or right) vagus nerve is usually attached to the œsophagus by the small mesentery and is normally well defined The anterior (or left) vagus nerve, however, sometimes splits into two or three separate branches, occasionally an intramural trunk may also be present, which must be secured

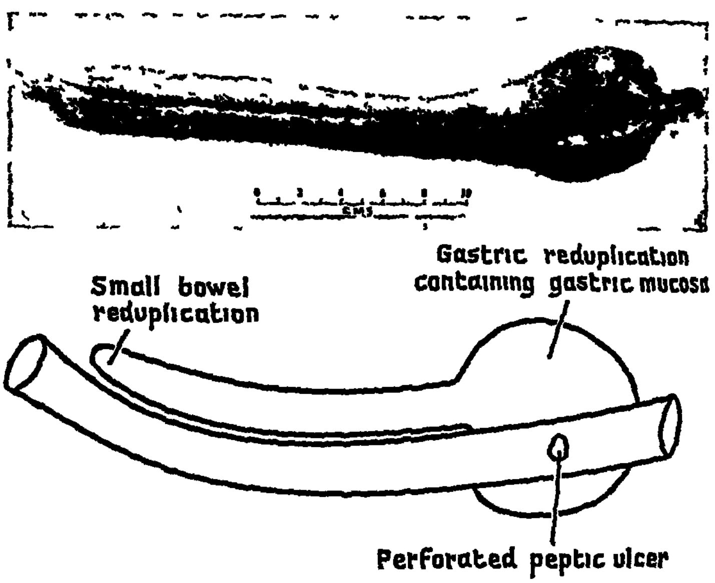
The (posterior) gastrojejunostomy should create a large stoma extending from the lesser to the greater curve at the junction of the body with the antrum Adequate drainage of the antrum is essential, as has been shown by Oberhelman and Dragstedt (1955) using a more realistic kind of test-meal These workers found that gastric retention leads to oversecretion of hormonal gastric juices, and they report that many of the poor results of vagotomy and gastrojejunostomy have been associated with what they call high gastrojejunostomy—one not sited to drain a hypotonic antrum

Complications

The complication most closely related to the operation itself is gastric stasis, which may last several days A routine has now been developed which has almost eliminated it Nasal aspirations are discontinued at the first possible moment, usually twenty-four hours after the operation, and prompt feeding of semi solids by mouth is allowed in most cases on the third postoperative day The giving of solid food seems to stimulate gastric activity and to promote restoration of normal intestinal function

GRADING OF 193 CASES

Grade	Male	Female	Total
Satisfactory			
I	127	14	141 (73%)
II	31	3	34 (17%)
IIIS	12	2	14 (7%)
Total	170	19	189 (98%)
Unsatisfactory			
IIIU	0	2	2 (1%)
IV	1	1	2 (1%)
Total	1	3	4 (2%)
Grand total	171	22	193



Gastric reduplication containing gastric mucosa
Small bowel reduplication
Perforated peptic ulcer

Fig 1—Reduplication of bowel with peptic ulcer

Gastric hypotonia can occasionally develop if the patient overeats immediately after discharge from hospital, 2 of the present patients ingested a very large meal within a fortnight of operation and had to be readmitted In these cases vomiting was the principal symptom The patients, however, settled down quickly under treatment with gastric aspirations and intravenous infusion

Occasional patients may have difficulty in swallowing for four to six weeks, but reassurance and the ingestion of semi-solid food during this period of difficulty allow the patient to thrive until the disability passes away

The symptoms of which patients complained at follow up were

Symptom	*No of patients complaining*
Pain	11
Diarrhœa	11
Symptoms of hypoglycæmia	3
Nausea and vomiting	6
Fullness and flatulence	10
Bilious vomiting	11

All these symptoms were slight except in 2 cases of bilious vomiting which necessitated entero anastomosis Radiography after a barium meal gave negative results (apart from continuing deformity of the duodenal cap) in all the patients with pain except 2 who had recurrent ulcers All the other symptoms were controlled by simple measures For example, the nausea complained of by 6 patients usually followed a heavy meal and was avoidable

Recurrences

The 2 recurrences are well worth describing because they show where the principles of the operation have been inadequately followed and have led to recurrence of the ulcer

Case 1 —A woman who was improved by the operation but a year after operation had fairly persistent pain *Radiography after a barium meal had been done twice in this patient*, but it was not until two years after operation that such radiography revealed a jejunal ulcer She was *admitted* for an insulin test meal, which indicated incomplete vagotomy, a finding which is useful in recurrent ulceration because it may indicate the cause of the recurrence The patient underwent exploratory laparotomy with a view to *partial gastrectomy* if necessary, but the anastomosis was satisfactory, with very little scarring, and no ulcer was found The lower end of the œsophagus was explored, and the anterior vagus trunk was found to be complete and was divided It is too soon to say whether this subsequent procedure has completely satisfied this patient

The other recurrence shows the danger of gastro-enterostomy which does not drain the gastric antrum satisfactorily Owing to some oversight, the anastomosis was placed rather high towards the fundus of the stomach and to the left of the usual site
